Possibly, as an oversight, they have omitted the importance of tetanus prophylaxis in such patients. That dog-bite wounds (and other animal bites, including insect bites) are tetanus-prone is supported by several reports in which these wounds were considered the foci of tetanal infections in patients with clinical tetanus.[1-3] In the report by Chambers and Payne, although cultures from the dog-bite wounds did not reveal *Clostridium tetani*, the possibility of this infection cannot be ruled out. Writers on the subject have consistently emphasized the difficulty in isolating these causative organisms from suspected foci of infections in patients *with* clinical tetanus. Even with the best techniques available, isolation of *C. tetani* organisms was successful in less than a third of 119 patients treated at the Mayo Clinic and related hospitals. Furthermore, since the patients reported by Chambers and Payne were members of the United States Armed Forces, they probably were adequately immunized against tetanus, as tetanus toxoid immunization is mandatory in the armed services. Such immunization would have prevented clinical tetanus in any of the patients who may have had tetanal infection complicating a dog-bite wound.

Thus, dog-bite wounds must be considered tetanus-prone and should be treated as such. When the bite is superficial and the wound is minor, careful cleansing, debridement, and proper dressings should be sufficient to prevent tetanus. Active immunization with tetanus toxoid can be started, and completed later, in any patient who has not been previously immunized. If the bite is serious enough to be considered an "infected crush wound," tetanal immunization, in addition to the treatment prescribed by Chambers and Payne, is necessary to prevent this dread disease. If the patient has not been previously immunized with tetanus toxoid, 250 units† of human tetanus hyperimmune globulin (human tetanus antitoxin) should be given intramuscularly when he is admitted to the physician's office or to the emergency room. Currently it is accepted policy to initiate active immunization at the same time. With another syringe and another site, the initial injection of 0.5 ml of mineral-absorbed tetanus toxoid (preferably) is given intramuscularly, and arrangements are made to complete the "basic series" later. This would mean a second injection within four to six weeks and a third injection within another six to 12 months. Dual injections of human tetanus antitoxin and tetanus toxoid (with completion of the basic series as prescribed) produce passive immunization that is prompt and effective and active immunization that is long-lasting and continuous.[5]

For the patient who has a significant dog-bite wound and who has been previously and appropriately immunized with tetanus toxoid (as can be assumed to have been true of all patients reported by the authors), in accordance with the guidelines for the medical profession regarding tetanus prevention as outlined at the International Conference on Tetanus[6] held in Bern, Switzerland, in 1966, a "wound booster" of 0.5 ml of tetanus toxoid is recommended if the interval since the "basic series" or a subsequent booster has been longer than one year.

It is my opinion that, with an immunologic agent as effective and dependable as tetanus toxoid, we can now eliminate the use of the "wound booster." Available evidence supports the impression that any patient who has re-

ceived the "basic series of tetanus toxoid" and an "interval reinforcement booster" of toxoid every five years thereafter can be considered continuously and adequately protected against tetanus during the five-year period. Admittedly, the considered five-year "safe interval" is arbitrary, and further experience and observations may lengthen this interval.[7] In the meantime, if the general plan of tetanus toxoid immunization as proposed is accepted and implemented, physicians, when treating patients who have contaminated wounds (including dog bites), could do as the authors did, namely, direct their full attention to the local care of these wounds without concern about tetanus.

Letter to the Editor

I cannot refrain from commenting on the article by Drs. Kiser, Peterson, and Johnson entitled "Open Heart Surgery in Elderly Patients," which was in the February 1969 issue of MINNESOTA MEDICINE.*

It certainly is of note that the four elderly patients reported in the article survived their operative procedures. In order to put this report in proper perspective, however, I believe there are three questions that should be answered. These are as follows:

1. What has been the long-term survival of these four patients?
2. How many other patients in this same age group have been operated on and have not survived surgery?
3. What are the objective data indicating hemodynamic improvement in these people?

Since each of the patients reported had heart catheterization preoperatively, it would be most useful to know more about the preoperative hemodynamic data than what was included in the report. A final bit of very useful information would be some statement as to the therapeutic programs these patients were following before their open heart surgery.

Paul Winchell, M.D.†
Minneapolis, Minnesota

---

*See page 231.
†Associate Professor, Department of Medicine, University of Minnesota.

In response to the questions raised by Dr. Paul Winchell regarding the article "Open Heart Surgery in Elderly Patients," the four patients reported were the *only* patients operated upon in this seventy to eighty age group at the time this report was submitted. Since that time, three other "eighth-decade" patients have undergone surgery for aortic valve replacement with one operative death. Of those patients reported in the article, the long-term survival has been 36 months, 16 months, 18 months and 12 months.

One of these patients expired during the recent "flu" epidemic of viral pneumonia when 16 months postoperative. Up until the time of his death, he was not limited by cardiac disease. An autopsy was performed and revealed no evidence of thrombosis, embolism, congestive heart failure or malfunction of the prosthesis. The remainder of the patients are presently living and functioning at an improved level.

The objective data to indicate hemodynamic improvement consists of absence of the previous clinical evidence of hemodynamic derangement and elevation of their functional classification. All of these patients, except one, were functional Class IV, and they were being treated with digitalis, diuretics and salt restriction.

In the interest of brevity, only that catheterization data thought to be relevant was included in the report. Indeed, there is some question whether cardiac catheterization is an absolute necessity prior to surgery in any of these patients.

Joseph C. Kiser, M.D,
Minneapolis, Minnesota

The Editor's Soliloquy

Purism

ALL OF US ARE M.D.'s and can qualify as experts in the field of medicine. From that vantage point we are fully competent to obtain a history, do a complete examination, make an evaluation, offer a diagnosis, and recommend treatment. How else can the doctor know what he is referring; or the patient know whom she needs to see, without the privilege of consulting the physician of her choice? Beyond that some of us may further qualify as specialists; but since that does not and should not remove us from the category of having a knowledge of general medicine, we need not assume the guise of purism in the staff room and practice something else in the office.

Some of my colleagues may proclaim in the hospital staff room such strict adherence to their specialty that they will accede to nothing but "cut and sew." To exceed that, they maintain, infringes on the private domain of the referring physician, the examining doctor, the diagnostician, or the laboratorian.

They may examine the area where they plan to cut, but a pelvic examination, for example, is in the realm of the gynecologist; the heart belongs to the cardiologist; the lungs are the pneumologist's forte. For the aching back consult the orthopedist; for the creaking joints, the rheumatologist; for the ingrown toenail, the podiatrist. If red blood cells appear in the urine, see the urologist; for a trace of sugar in the urine confer with the diabetologist. It may become poltroon.

Within the sanctuary of their private offices, however, some professional purists may prescribe for a case of walking pneumonia; give a tranquilizing pill or two for the jitters, some sleeping pills for insomnia, an antacid for dyspepsia, a gargle for a sore throat, a salve for dermatitis, or maybe even a flu shot. Or they may conceivably go so far as to cavalierly recommend a six-week holiday away from the nagging spouse—to avoid a nervous breakdown: a better ploy than seeing a psychiatrist—and cheaper!

On the other hand, the non-surgical specialist may apply a butterfly dressing for a laceration (provided it doesn't exceed an inch or two), a medically-treated bandage for a sprain, a plaster for a lumbago back, or he may even presume to watch or give a hormone shot for a lump that shouldn't be there.

Medicine is a humanitarian profession wherein protocol should not be so rigid that the specialist cannot ethically double as an adviser on simple medical problems when the need arises—for the convenience and reassurance of the patient. Despite progressively narrowing specialization, boundaries should always remain flexible. For a specialist to step outside his specific province on occasion is creditable; but to disavow doing so is hypocritical.

painful night
leg cramps...
respond to specific
therapy with
QUINAMM™
(Quinine sulfate, 260 mg.,
Aminophylline, 195 mg.)

THE BETTMANN ARCHIVE

Just one tablet at bedtime • Prevents painful night leg cramps • Permits restful sleep

How many of your patients stamp their feet at night and lose sleep because of painful leg cramps? Unless prompted, they usually fail to report this distressing condition and suffer needlessly.

One tablet of QUINAMM at bedtime usually controls distressing night cramps and permits restful sleep with the initial dose.

Prescribing information—Composition: Each white, beveled, compressed tablet contains: Quinine sulfate, 260 mg., Aminophylline, 195 mg. **Indications:** For the prevention and treatment of nocturnal and recumbency leg muscle cramps, including those associated with arthritis, diabetes, varicose veins, thrombophlebitis, arteriosclerosis and static foot deformities. **Contraindications:** QUINAMM is contraindicated in pregnancy because of its quinine content. **Side Effects/Precautions:** Aminophylline may produce intestinal cramps in some instances, and quinine may produce symptoms of cinchonism, such as tinnitus, dizziness, and gastrointestinal disturbance. Discontinue use if ringing in the ears, deafness, skin rash, or visual disturbances occur. **Dosage:** One tablet upon retiring. Where necessary, dosage may be increased to one tablet following the evening meal and one tablet upon retiring. **Supplied:** Bottles of 100 and 500 tablets.

Curbstone Consultation

Rectal Carcinoids

QUESTION: I recently did a sigmoidoscopic examination on a 68-year-old male patient and at 12 cm. from the anal verge I encountered a small 0.5-cm. submucosal nodule on the posterior wall of the rectum. This was an incidental finding and at the time of biopsy I thought the lesion was probably an adenomatous polyp and removed the entire specimen through the scope. Histological sections, however, showed the lesion to be a carcinoid tumor. The patient does not exhibit symptoms of such a syndrome. Because of associated respiratory and cardiac conditions I feel he would not tolerate a major surgical procedure. What course of therapy would you advise?

ANSWER: Controversy exists as to whether rectal carcinoids have malignant potential. There is little justification for such doubts, however, since cases have been reported showing indisputable evidence of malignant changes, and in some cases metastases have been demonstrated. Nevertheless, foregut and hindgut carcinoids are usually benign, histologically and biochemically, as opposed to carcinoids of the ileum which frequently take on malignant characteristics and exhibit the carcinoid syndrome.

Size seems to be an important factor as to malignant potential in rectal carcinoids. When less than 1.0 cm. in size such tumors may be treated as benign, and local excision can be considered adequate. In lesions measuring more than 2.0 cm., radical surgery should be considered. Because of its small size and the fact that all the tumor in the instant case was removed, treatment can be considered sufficient. The patient should be followed by periodic proctoscopic examinations, however, and if local recurrence occurs more radical surgery should be considered.

...you have a lot going for you in the wide range of bacterial infections.

PRESCRIBING INFORMATION. For complete information consult Official Package Circular. **Indications:** Infections due to susceptible strains of Gram-negative bacteria (including Shigellae, *S. typhosa* and other Salmonellae, *E. coli, H. influenzae, P. mirabilis, N. gonorrhoeae* and *N. meningitidis*) and Gram-positive bacteria (including streptococci, pneumococci and nonpenicillinase-producing staphylococci).

Contraindications: A history of allergic reactions to penicillins or cephalosporins and infections due to penicillinase-producing organisms.

Precautions. Typical penicillin-allergic reactions may occur, especially in hypersensitive patients. Mycotic or bacterial superinfections may occur. Experience in newborn and premature infants is limited and caution should be used in treatment, with frequent organ function evaluations. Safety for use in pregnancy is not established. In gonorrheal therapy, serologic tests for syphilis should be performed initially and monthly for 4 months. Assess renal, hepatic and hematopoietic function intermittently during long-term therapy.

Adverse Reactions: Skin rash, pruritus, urticaria, nausea, vomiting, diarrhea and anaphylactic reactions. Mild transient elevations of SGOT or SGPT have been noted. Black tongue has been noted in some patients receiving the Chewable Tablets.

Usual Dosage: Adults—250 or 500 mg. q. 6 h. (according to infection site and offending organisms). Children—50-100 mg./Kg./day in 3 to 4 divided doses (depending on infection site and offending organisms). Bacterial meningitis —150-200 mg./Kg./day in 6 to 8 divided doses. Children weighing more than 20 Kg. should be given an adult dose when prescribing orally. In parenteral administration, children weighing more than 40 Kg. should be given an adult dose. Beta-hemolytic streptococcal infections should be treated for at least 10 days.

Supplied: Capsules—250 mg. in bottles of 24 and 100. 500 mg. in bottles of 16 and 100. For Oral Suspension—125 mg./5 ml. in 60, 80 and 150 ml. bottles. 250 mg./5 ml. in 80 and 150 ml. bottles. Chewable Tablets—125 mg. in bottles of 40. Injectable—for I.M./I.V. use—vials of 125 mg., 250 mg., 500 mg., and 1 Gm. Pediatric Drops—100 mg./ml. in 20 ml. bottles.

The penicillin you use like a broad-spectrum antibiotic

now she can cope…

thanks to

Butisol SODIUM®
(SODIUM BUTABARBITAL)

the "daytime sedative" for everyday situational stress

When stress is situational—environmental pressure, worry over illness—the treatment often calls for an anxiety-allaying agent which has a prompt and predictable calming action and is remarkably well tolerated. Butisol Sodium (sodium butabarbital) meets this therapeutic need.

After 30 years of clinical use . . . still a first choice among many physicians for dependability, safety and economy in mild to moderate anxiety.

Contraindications: Porphyria or sensitivity to barbiturates.

Precautions: Exercise caution in moderate to severe hepatic disease. Elderly or debilitated patients may react with marked excitement or depression.

Adverse Reactions: Drowsiness at daytime sedative dose levels, skin rashes, "hangover" and systemic disturbances are seldom seen.

Warning: May be habit forming.

Usual Adult Dosage: As a daytime sedative, 15 mg. (¼ gr.) to 30 mg. (½ gr.) t.i.d. or q.i.d.

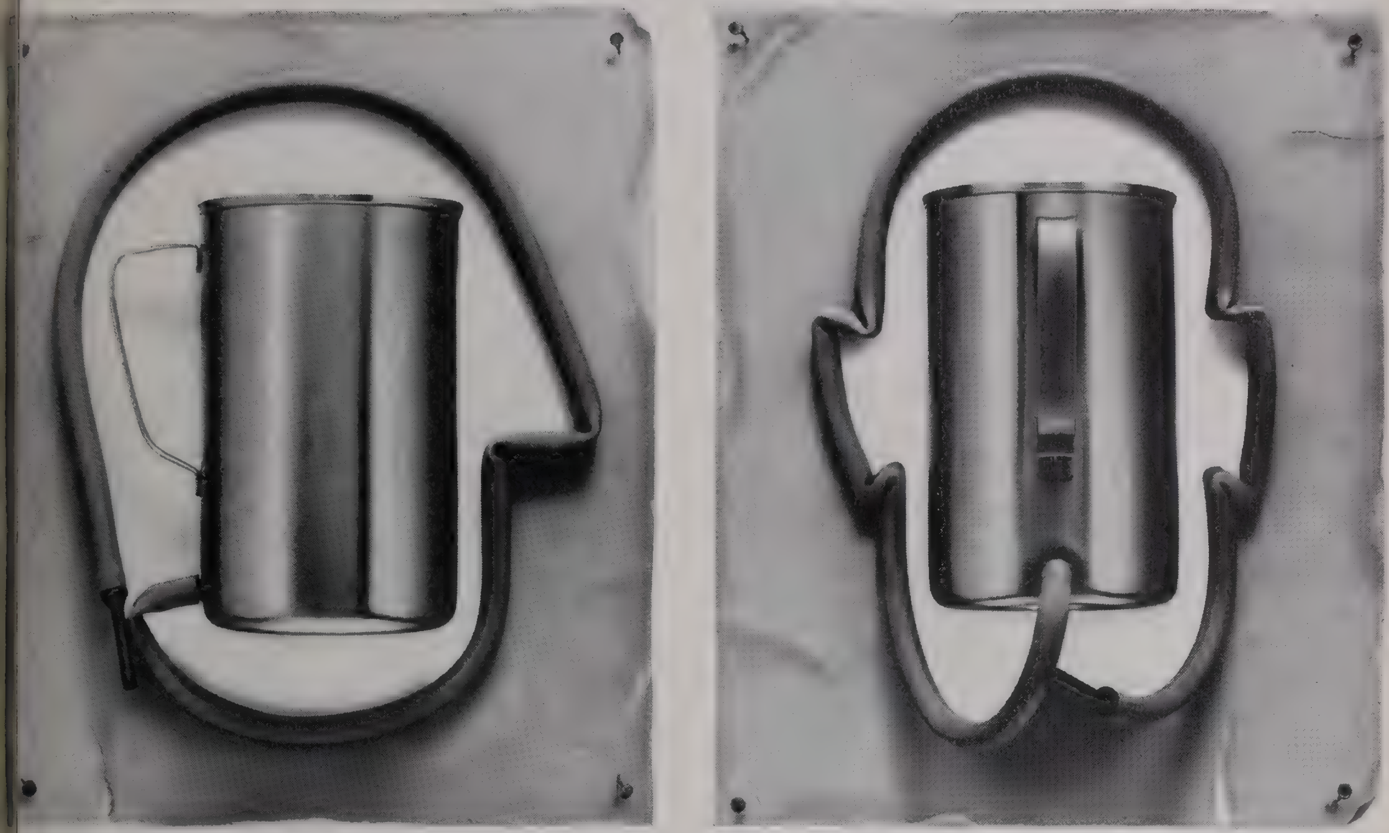
Available for daytime sedation: Tablets, 15 mg. (¼ gr.), 30 mg. (½ gr.); Elixir, 30 mg. per 5 cc. (alcohol 7%).

BUTICAPS® [Capsules Butisol Sodium (sodium butabarbital)] 15 mg. (¼ gr.), 30 mg. (½ gr.).

McNEIL

McNeil Laboratories, Inc., Fort Washington, Pa.

Public Enema No.1



Caim the rewards of sparing your patients the tubes ad tribulations of unpleasant enemas.

Cmpared to enemas, Dulcolax suppositories are a gntler and simpler way to empty the bowel. Gone ae the tubing, the "accidents", and the bruised egos. Jst one suppository, inserted against the bowel wall, uually brings about an evacuation within 15 minutes to an hour.

In the hospital, order Dulcolax for constipation or bowel cleansing. Your patients will often prefer it to embarrassing enemas. And you can be sure nurses will appreciate the saving in time and effort.

Dulcolax tablets taken at night usually result in a bowel movement the following morning. A combination of tablets at night and a suppository the next morning generally cleans the bowel thoroughly in preparation for surgery or special procedures. Keep in mind, however, that the drug is contraindicated in the acute surgical abdomen.

Dulcolax®...it's predictable

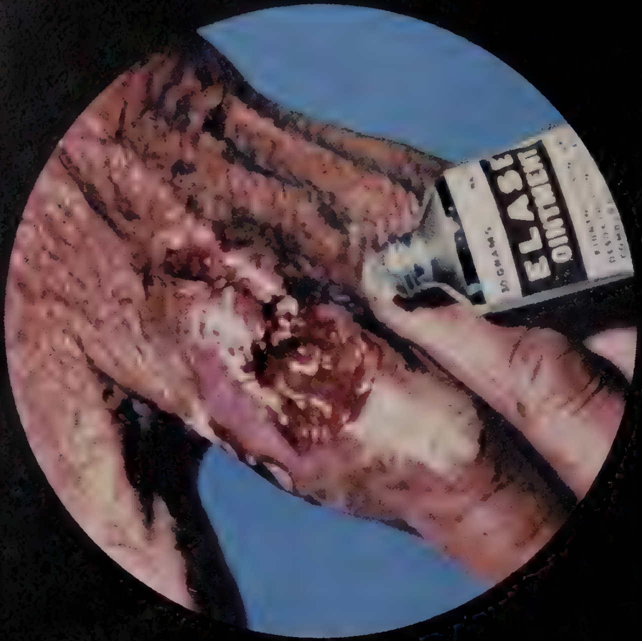
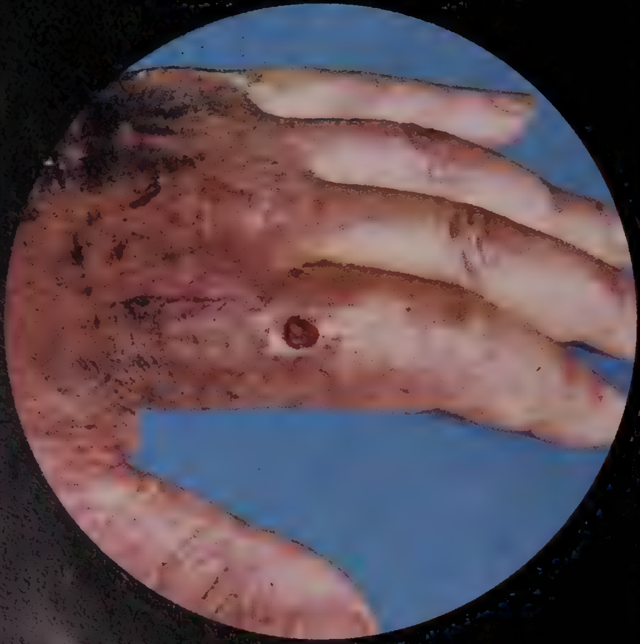
this ulcer did not heal...until its surface was cleared of dead tissue and debris



FIRST APPLICATION
ELASE Ointment is applied to a deep ulceration of a finger.

EIGHTEEN DAYS LATER
Healing has progressed rapidly without interruption or interference from any accumulated purulence or necrotic tissue. Greatly reduced size of lesion and minimal scar tissue indicate quality and vigor of healing which is almost complete.



to aid in debridement
to facilitate healing
in chronic cutaneous ulcers...

Elase® Ointment

(fibrinolysin and desoxyribonuclease, combined, [bovine] ointment)

PARKE-DAVIS

By helping to remove dead tissue and debris from the ulcer's surface, ELASE Ointment creates a better environment for the elimination of infection, for healthy granulation... *for healing.* Its lytic enzymes effectively break down DNA in dead leukocytes and other debris... the fibrin in blood clots, serum, and purulent exudates... and the denatured proteins in necrotic tissue. Protein elements of *living* tissue are relatively unaffected. ELASE Ointment is indicated in stasis ulcers and in other infected or inflamed ulcers caused by circulatory disturbances. In cases requiring skin grafting, it is used preoperatively for debridement. For ambulatory patients debridement with ELASE Ointment is a convenient therapy and a regimen likely to be followed. *Precautions:* Observe usual precautions against allergic reactions, particularly in persons with a history of sensitivity to materials of bovine origin or to mercury compounds. *Adverse Reactions:* Side effects attributable to the enzymes have not been a problem at the dose and for the indications recommended. *Discussion:* Successful use of enzymatic debridement depends on several factors: (1) dense, dry eschar, if present, should be removed surgically before enzymatic debridement is attempted; (2) the enzyme must be in constant contact with the substrate; (3) accumulated necrotic debris must be periodically removed; (4) the enzyme must be replenished at least once daily; and (5) secondary closure or skin grafting must be employed as soon as possible after optimal debridement has been attained. It is further essential that wound-dressing techniques be performed carefully under aseptic conditions and that appropriate systemically acting antibiotics be administered concomitantly if, in the opinion of the physician, they are indicated. *Available:* ELASE Ointment is supplied in 30-Gm. tubes containing 30 units (Loomis) of fibrinolysin and 20,000 units of desoxyribonuclease with 0.12 mg. thimerosal (mercury derivative); and in 10-Gm. tubes containing 10 units of fibrinolysin and 6,666 units of desoxyribonuclease with 0.04 mg. thimerosal. ELASE Ointment has a special base of liquid petrolatum and polyethylene; contains sodium chloride and sucrose used during manufacture; is stable at room temperature through the expiration date stated on the package.

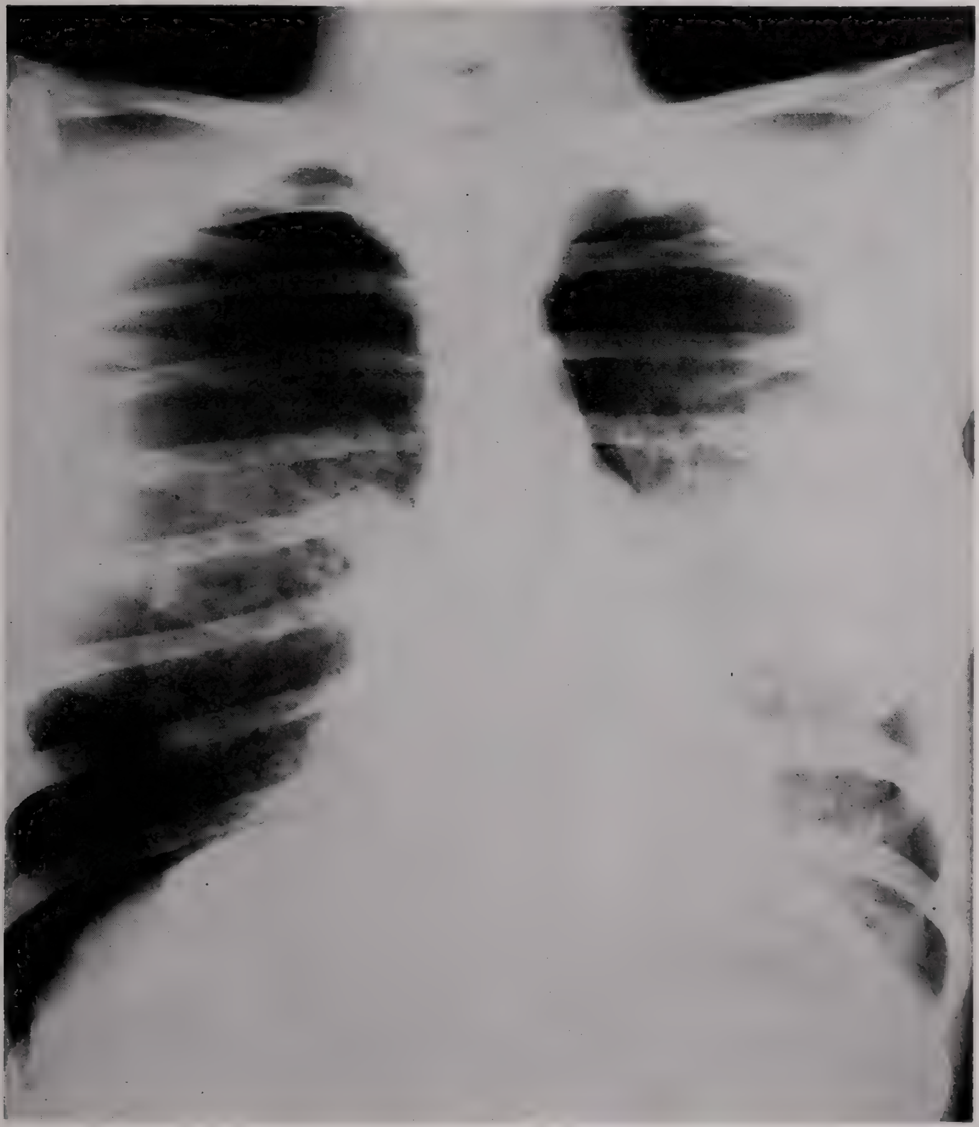
Dyspnea in a Teen-age Girl

THIS 13-YEAR-OLD school girl complained of moderate dyspnea and dry cough. She had been feeling generally ill for several days. On examination, scattered skin lesions were present on the head and neck, described as healing vesicles. WBC was 14,000. There was no fever. The chest x-ray taken on admission is shown (Figure).

What is your diagnosis? (See next page.)



Figure

Diagnosis: Pulmonary histiocytosis with spontaneous pneumothorax.

Clinical Course

The bilateral spontaneous pneumothorax was readily apparent. Chest tubes were inserted bilaterally, but the pneumothorax proved difficult to manage. It recurred and replacement of tubes was required several times. Lung fields consistently showed a fine granular infiltration and a cystic appearance.

About four weeks after admission, left thoracotomy was done and the left lung biopsied. The lung was grossly abnormal in appearance during the surgical procedure, and several subpleural cysts were seen to rupture spontaneously while the lung was under observation. The histological diagnosis of the lung tissue was histiocytosis; skin tissue from the neck lesions showed similar abnormalities.

Discussion

Eosinophilic granuloma, Hand-Schueller-Christian and Letterer-Siwe syndromes are older terms designating portions of the spectrum of diseases included under the more general term, histiocytosis. These diseases are seen most commonly in white children in the first decade of life; the most severe form of the disease, Letterer-Siwe syndrome, in the first year of life. Skeletal involvement may be the only manifestation of histiocytosis (eosinophilic granuloma), and overall, bony lesions are present in 80% of the cases.[1]

Pulmonary histiocytosis is usually associated with widely disseminated disease, but a few cases of what appear to be primary pulmonary histiocytosis have been described.[2] These have tended to be in adults, usually in males. Several patients have presented with spontaneous pneumothorax.

The outlook for patients with pulmonary histiocytosis is extremely variable, but generally quite prolonged. The pulmonary form can result in fibrotic changes and chronic pulmonary disability.

Induction of Labor by Intra-amniotic Injection of Hypertonic Solutions*

INJECTION OF HYPERTONIC SOLUTIONS into the amniotic cavity is not a new technique for induction of labor. While studying the problem of induction in cases of therapeutic abortion, fetal death in utero, or potentially lethal fetal anomalies, Aburel[1] discovered that the injection of 33% saline was an effective means of terminating the pregnancy. Boero[2] was impressed by the clinical observation that, when pregnancy was complicated by a serious medical condition such as tuberculosis or heart disease, spontaneous death of the fetus frequently led to improvement in the mother's condition. Therefore, as a method for terminating fetal life, he used injection of 2 to 3 ml of formalin into the amniotic fluid. At about the same time, Burke[3] noted that labor was frequently induced when radiopaque contrast medium was injected in attempts to diagnose placenta praevia by amniography. Subsequently, Playfair[4] used this same method to induce labor in 115 normal-term pregnancies with very poor results; induction occurred in all but four of these patients, but there were 16 fetal deaths and one maternal death. Playfair (cited by Fuchs[1]) later reported injection of 50% glucose solution into the amniotic cavity.

In 1948, while trying to find a simpler method of inducing labor in cases of fetal death in utero, Portes and associates[5] discovered that simply distending the uterus with isotonic saline was frequently effective. The intra-amniotic injection of hypertonic saline for induction of labor became widely used in Japan after legalization of abortion there in 1948. However, between 1948 and 1950 at least 25 maternal deaths in Japan were attributed to this technique, and the complication rate following its use was stated to be 50%.[6] These poor results were attributed by Wagatsuma[6] to use of the method by inadequately trained persons and to poor selection of patients. The experiences of the Japanese with hypertonic saline essentially stopped all further progress with this technique for the next 10 to 15 years.

By the late 1950s and early 1960s, active surgical management was the primary form of treatment for therapeutic or legal middle-trimester abortion, as well as for the management of missed abortion. The rebirth of interest in the hypertonic saline method for induction of labor and its eventual clinical application began in 1962. At that time, Bengtsson and Csapo[7] used this method to suppress placental formation of progesterone in an effort to verify Csapo's[8] theory of progesterone block control of the pregnant uterus.

Procedure

Transvaginal

The hypertonic solution can be injected either transvaginally or transabdominally. The transvaginal route is recommended by some for pregnancies of 13 to 20 weeks' gestation, whereas the abdominal approach is preferred in more advanced pregnancies. For the vaginal approach, the unanesthetized patient is placed in the lithotomy position and then prepared and draped as for any vaginal procedure. The bladder is emptied prior to further instrumentation. The cervix is then pulled down, and an appropriate needle is inserted through the anterior wall of the cervix just below the junction with the bladder so that the needle forms an angle of 15 to 20° with the axis of the cervix. When free flow of amniotic fluid through the needle has been established, as much fluid as possible is allowed to escape before the hypertonic solution is injected.

---

*This paper was prepared under the supervision of members of the faculty of the Mayo Graduate School of Medicine.

Transabdominal

When the transabdominal route is used, the patient is placed in the supine position and the abdomen is prepared and draped as for laparotomy. The procedure is then similar to that of amniocentesis, with use of local anesthesia in the form of a skin wheal through which the needle is inserted in the midline halfway between the symphysis and the fundus of the uterus. Again, the amniotic fluid is withdrawn before injection of the hypertonic solution.

General Principles

Certain general principles in the performance of this procedure, whether via the vaginal or the abdominal route, should be stressed. First, strict adherence to sterile technique is mandatory. Second, most investigators currently prefer to use 20% sodium chloride solution for intra-amniotic injection; the use of 50% glucose for induction of labor is not as acceptable because of the greater likelihood of infection with this material. Third, the amount of hypertonic solution injected into the amniotic cavity should be equal to the volume of amniotic fluid removed, up to a maximum of 200 ml. Fourth, it is advantageous to know the approximate amount of amniotic fluid present at various early stages of pregnancy. Wagner and Fuchs[9] derived a formula which provides such an approximation: the average volume of amniotic fluid at 15 weeks' gestation is 125 ml; for each week prior to 15 weeks, down to 11 weeks, subtract 25 ml; for each week after 15 weeks, add 50 ml. Fifth, the patient should be fully awake during the procedure in order to be able to report any unusual symptoms such as pain, dizziness, marked thirst, or sudden sensation of heat in the upper part of the body which would suggest intramyometrial or intravascular injection. The injection itself should be performed slowly, at a rate of 2 to 4 ml/min. Finally, this procedure should be used only in obstetrical units and should be performed by competent experienced personnel.

Evaluation of Method

The basic clinical studies of this technique were done by Bengtsson and Csapo[7] using two different groups of patients—normal middle-trimester patients who were to have legal abortions, and patients with fetal deaths in utero or missed abortions.

In the middle-trimester patients undergoing legal abortions, the following results were obtained. Prior to the intra-amniotic injection of hypertonic saline, the base-line active pressure of the uterus was very low, averaging 4 mm Hg. During the first three hours after the injection, when the induced hypertonicity was maximal, the average increase in active uterine pressure was only 2 mm Hg. Likewise, no significant increase in uterine activity was noted during this time. By 16 to 22 hours after the injection, when the induced hypertonicity had diminished to an insignificant level, the intra-amniotic pressure had reached an average value of 30 mm Hg. The process of evolution of uterine activity was partially completed by 16 to 22 hours after injection, as indicated by detectable changes in the cervix. However, further evolution of uterine activity was required for clinical progress, as indicated by the fact that the average time from injection to abortion was 34 ± 5 hours.

The peak intra-amniotic pressures recorded after injection of hypertonic saline were in the range of 60 to 90 mm Hg, which are comparable to or greater than the pressures recorded during normal labor at term. On the other hand, the same maximal working capacity of the uterus could not be achieved in normal middle-trimester pregnancies by using oxytocin alone, even though the infusion rates were unlimited. Once clinical labor began after injection of hypertonic saline, it was of surprisingly short duration, usually two to three hours until abortion occurred. Interestingly enough, it has been established[7] and confirmed[10] that the time from injection to abortion can not be shortened by the administration of oxytocin. This is thought to be due to the fact that the hypertonic solution has already elicited the maximal working capacity of the uterus and, therefore, the addition of oxytocin stimulation produces no further effect. On the other hand, the systemic administration of progesterone appears to delay the process of evolution of uterine activity and thereby prolong the injection-to-abortion interval.

In the group of patients with fetal deaths in utero or missed abortions, development of uterine activity occurred more rapidly. The injection-to-abortion interval averaged 13.5 hours. However, the process of evolution of uterine activity went through the same pattern of development in both groups—namely, a delayed, gradual change from local, nonpropagating, asynchronous uterine activity to a stage of synchronous, propagative uterine activity. The addition of oxytocin stimulation in this group of patients also did not shorten the injection-to-abortion interval.

TABLE

Summary of Reported Results of Intra-amniotic Injection of Hypertonic Solution for Induction of Labor

Investigators	No. of patients	Latent period (hr)		Active labor (hr)	Success rate (%)
		In patients with therapeutic abortions			
Bengtsson and Csapo[7]	30		33*		100
Wagner and associates[10]	239		36.5*		94
Gochberg and Reid[11]	26		36.5*		85
Jaffin and associates[12]	6	21.3		1.8	100
Weingold and associates[13]	27	22.6		2.8	100
Kerr and associates[14]	16	18.3		8.4	75
		In patients with fetal death in utero			
Bengtsson and Csapo[7]	15		14*		100
Jaffin and associates[12]	6	14.3		1.8	100
Weingold and associates[13]	9	18.2		1.3	100
Kerr and associates[14]	9	18.3		8.4	89

*These data are overall injection-to-abortion interval.

In a similar group of patients with fetal death in utero, the use of oxytocin stimulation alone for periods of 14 to 24 hours failed to produce completion of abortion in the majority of cases and clinical progress could not be demonstrated during the infusion period. After the intra-amniotic injection of hypertonic saline there was a uniform pattern of labor consisting of a painless latent period during which cervical effacement occurred, followed by a short, active period of high-intensity contractions which usually resulted in a complete abortion with minimal loss of blood.

The validity of Bengtsson and Csapo's work has been confirmed by other investigations (Table).

Mechanism of Action

Four hypotheses have been advanced to explain this phenomenon:

1. The hypertonic solution alters the morphology of the placenta and thereby affects placental endocrine function and its control over the pregnant uterus.
2. Uterine volume is increased due to alterations in amniotic fluid volume in an attempt to achieve equilibrium with the hypertonic solution.
3. There may be an indirect neuroendocrinologic action produced, which affects the hypothalamus and neurohypophysis, causing an increase in endogenous secretion of antidiuretic hormone and oxytocin.
4. There may be a direct effect of the hypertonic solution on the fetal membranes or myometrium.

A working theory combining the first two of these possible mechanisms is by far the most logical explanation for the effectiveness of this technique. The basis for such an explanation lies in Csapo's[15] development of the progesterone block theory proposed in the 1950s. Csapo and co-workers[16] stated that effective uterine activity was controlled by the ratio of uterine volume to the concentration of progesterone in the myometrium (V/P_m). According to this theory, both uterine volume and placental progesterone concentration increase during normal pregnancy. The pregnancy is maintained as long as the ratio of V/P_m remains small; however, when this ratio reaches a certain critical value, the pregnancy terminates. Furthermore, it is the myometrial progesterone concentration, P_m, which is the "defense mechanism" of pregnancy because of its ability to suppress intrinsic activity and pharmacologic reactivity of the pregnant uterus. Therefore, the effectiveness of intra-amniotic injection of hypertonic solutions for the induction of uterine activity is thought to be due to two actions. First, the uterine volume is increased due to an increase in amniotic fluid volume. Second, the hypertonic solution damages the placental structure, causing a decrease in production and transport of progesterone, resulting in a weakening of the progesterone block or a partial progesterone withdrawal. The result of each of these changes is to increase the ratio V/P_m, which favors the evolution of uterine activity.

Some laboratory data are available to support this hypothesis. With regard to the increase in uterine volume following introduction of hypertonic saline, it has been shown that the volume increases by an average of 25 to 30% within three hours after injection.[17] Gochberg and Reid[11] used ^{131}I-labeled serum albumin in the hypertonic saline and demonstrated increases in amniotic fluid volume of 50 ml within 2½ hours, 115 ml in 5½ hours, and 145 ml by eight hours after injection. The injection-to-abortion interval can be doubled, from 36 hours to 77 hours, by the administration of progesterone prior to injection of hypertonic saline.[7]

Wiest and his group,[18] as well as Short and co-workers,[19] have shown a 33 to 45% decrease in the concentration of progesterone in the peripheral plasma after intra-amniotic injection of hypertonic saline. (This work could not be confirmed by Kerr and his group[14] who were using 50% glucose as the hypertonic solution.) The shorter injection-to-abortion interval for patients with fetal death in utero or missed abortion, in comparison to patients undergoing elective middle-trimester abortion, indicates the significance of the normal progesterone potential of the placenta. Finally, correlation of the pathologic changes in the placenta with the clinical results obtained tends to verify the hypothesis that the hypertonic saline causes progesterone withdrawal.

Pathology

Strauss[20] studied the effects of hypertonic saline on the placenta, decidua, and fetal membranes of eight middle-trimester-abortion patients. Gross examination of the placenta revealed subchorionic zones of severe intervillous stasis over the entire surface of the placenta. On microscopic examination, the amnion appeared to be destroyed by an autolytic process. The chorionic villi showed variable damage with intervillous stasis, fresh thromboses, and large numbers of polymorphonuclear leukocytes. The trophoblast was frequently destroyed completely. The deeper portions of the placenta appeared normal, and the decidua showed occasional areas of necrosis and hemorrhage.

Electron microscopy has corroborated these pathologic changes. Thus, there is a necrotizing placentitis produced in the layers directly beneath the fetal surface of the placenta. The deeper layers, near the maternal surface, appear to remain normal, and no consistent lesions could be demonstrated in the fetuses examined. It is assumed that these severe structural changes in the placenta alter the production, transport, and concentration of progesterone, resulting in a progesterone-withdrawal effect which in turn causes evolution of uterine activity.

Clinical Aspects

From a clinical standpoint, one must weigh the inherent risks against the advantages to be gained from the use of this method to induce labor.

The Major Risks

The major risks involved include the possible introduction of infection into the amniotic cavity, the possibility of a direct intravascular injection of the saline, the possibility of fetal erythrocytes entering the maternal circulation due to damage of the placental vessels, and the possibility of injury to the bowel or bladder.

The Advantages

The advantages, on the other hand, seem to be numerous. The procedure is relatively simple to perform and is associated with a high success rate and a low incidence or morbidity. The induced labor is rather painless, and the injection-to-abortion interval is relatively short. In cases of therapeutic abortion beyond 12 weeks' gestation, the need for hysterotomy is obviated along with any risk to future childbearing, due to a scarred uterus. In cases of missed abortion or fetal death in utero, this method is useful in that with early induction of labor the risk of potential hypofibrinogenemia and the inevitable psychic trauma can be minimized.

Summary

The use of intra-amniotic injection of hypertonic solutions for the induction of labor appears to be uniformly effective and rapid and presents a minimum of disadvantages. It would seem to be an ideal method for the management of middle-trimester therapeutic abortion, fetal death in utero, or missed abortion. However, its use should be restricted to obstetrical units, and it should be performed only by personnel familiar with the technique.

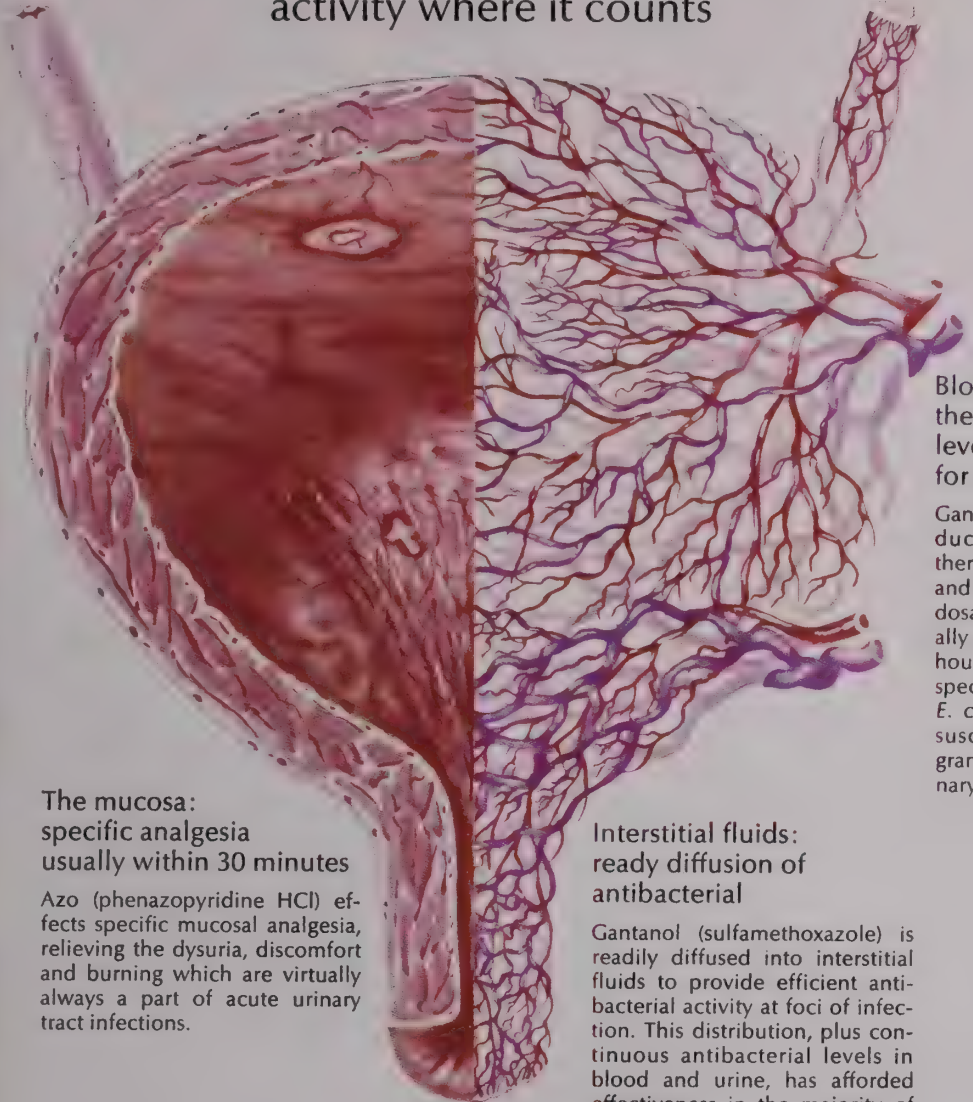
Imagination

One quality in which adult humanity is most deficient is imagination. All children have it; most adults have retained only scanty remnants. Perhaps our materialistic culture regards imagination as unmanly or morbid; or maybe imagination can germinate and flourish only in a fresh renaissance culture—which ours isn't. I often wonder whether practical scientists and technicians don't consciously stifle their remnants of imagination or unconsciously permit them to wither away. For instance, if I say that the top of my head feels as if it's floating or that the inside of my neck feels lumpy, my meaning is doubtless incomprehensible because of the listener's failure of imagination. (When I specify the inside of my neck, I mean the area between my throat and the outside of my neck.) Maybe my terseness is too surprising and hence disconcerting; perhaps it would be less confounding for me just to say: "I have a 'funny feeling' in my head or in my neck."—E.

Inner Sites...

In Cystitis...Azo Gantanol® focuses analgesic-antibacterial activity where it counts



Blood and urine: therapeutic antibacterial levels within 2 hours for up to 12 hours

Gantanol (sulfamethoxazole) produces prompt and prolonged therapeutic levels, in both blood and urine, with convenient *b.i.d.* dosage. Clinical response is usually obtained within 24 to 48 hours. The wide antibacterial spectrum of Gantanol includes *E. coli* and a variety of other susceptible gram-negative and gram-positive pathogens in urinary tract infections.

The mucosa: specific analgesia usually within 30 minutes

Azo (phenazopyridine HCl) effects specific mucosal analgesia, relieving the dysuria, discomfort and burning which are virtually always a part of acute urinary tract infections.

Interstitial fluids: ready diffusion of antibacterial

Gantanol (sulfamethoxazole) is readily diffused into interstitial fluids to provide efficient antibacterial activity at foci of infection. This distribution, plus continuous antibacterial levels in blood and urine, has afforded effectiveness in the majority of infections in which it has been used.

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Urinary tract infections with associated pain or discomfort when due to susceptible organisms; prophylactically in urologic surgery, catheterization and instrumentation.

Contraindicated in sulfonamide-sensitive patients, pregnant females at term, premature infants, newborn infants during the first three months of life, glomerular nephritis, severe hepatitis, uremia and pyelonephritis of pregnancy with gastrointestinal disturbances.

Warnings: Use only after critical appraisal in patients with liver damage, renal damage, urinary obstruction or blood dyscrasias. If toxic or hypersensitivity reactions or blood dyscrasias occur, discontinue therapy. In intermittent or prolonged therapy, blood counts and liver and kidney function tests should be performed.

Precautions: Observe usual sulfonamide therapy precautions including maintenance of an adequate fluid intake. Use with caution in patients with histories of allergies and/or asthma. Patients with impaired renal function should be followed closely since renal impairment may cause excessive drug accumulation. Occasional failures may occur due to resistant microorganisms. Not effective in virus and rickettsial infections.

Adverse Reactions: Headache, nausea, vomiting, urticaria, diarrhea, hepatitis, pancreatitis, blood dyscrasias, neuropathy, drug fever, skin rash, Stevens-Johnson syndrome, injection of the conjunctiva and sclera, petechiae, purpura, hematuria or crystalluria may occur, in which case the dosage should be decreased or the drug withdrawn.

Azo Gantanol®

(Each tablet contains 0.5 Gm sulfamethoxazole and 100 mg phenazopyridine HCl.)

PRELUDIN
PHENMETRAZINE
HYDROCHLORIDE

Preludin® phenmetrazine hydrochloride

Preludin is indicated only as an anorexigenic agent in the treatment of obesity. It may be used in simple obesity and in obesity complicated by diabetes, moderate hypertension (see Precautions), or pregnancy (see Warning).

Contraindications: Severe coronary artery disease, hyperthyroidism, severe hypertension, nervous instability, and agitated prepsychotic states. Do not use with other CNS stimulants, including MAO inhibitors.

Warning: Do not use during the first trimester of pregnancy unless potential benefits outweigh possible risks. There have been clinical reports of congenital malformation, but causal relationship has not been proved. Animal teratogenic studies have been inconclusive.

Precautions: Use with caution in moderate hypertension and cardiac decompensation. Cases involving abuse of or dependence on phenmetrazine hydrochloride have been reported. In general, these cases were characterized by excessive consumption of the drug for its central stimulant effect, and have resulted in a psychotic illness manifested by restlessness, mood or behavior changes, hallucinations or delusions. Do not exceed recommended dosage.

Adverse Reactions: Dryness or unpleasant taste in the mouth, urticaria, overstimulation, insomnia, urinary frequency or nocturia, dizziness, nausea, or headache.

Dosage: One 25 mg. tablet b.i.d. or t.i.d. Or one 75 mg. Endurets tablet a day, taken by midmorning.

Availability: Pink, square, scored tablets of 25 mg. for b.i.d. or t.i.d. administration, in bottles of 100 and 1000.

Pink, round Endurets® prolonged-action tablets of 75 mg. for once-a-day administration, in bottles of 100 and 1000. (B)R3-46-560-B

Under license from Boehringer Ingelheim G.m.b.H.

For complete details, please see full prescribing information.

She runs
good chance
# of losing
weight.

Exercise and Preludin run together in helping patients to lose weight.

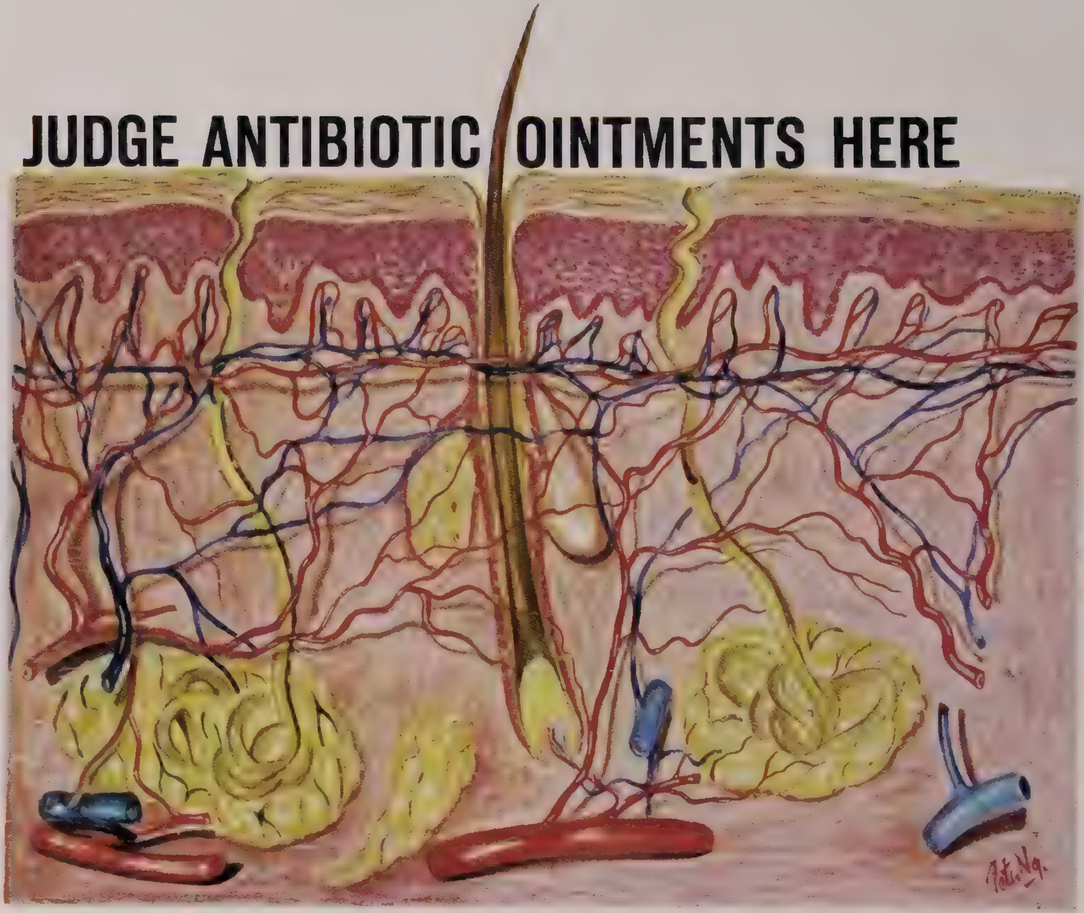
Preludin often puts a curb on appetite and promotes a sense of well-being. By boosting a dieter's spirit, Preludin may help patients get the exercise you may prescribe.

One Endurets tablet taken between breakfast and midmorning usually provides daylong and early-evening suppression of appetite.

A few patients may experience overstimulation or insomnia. For a brief summary of all adverse reactions, precautions, warning and contraindications, please see the adjoining page.

Preludin® phenmetrazine hydrochloride Endurets® prolonged-action tablets

JUDGE ANTIBIOTIC OINTMENTS HERE



Results on skin are final proof of any topical antibiotic's effectiveness

No in vitro test can duplicate a clinical situation on living skin. 'Neosporin' (polymyxin B—bacitracin—neomycin) Ointment has consistently proven its effectiveness in thousands of cases of bacterial skin infection. The spectra of the three antibiotics overlap in such a way as to provide bactericidal action against most pathogenic bacteria likely to be found topically. Diffusion of the antibiotics from the special petrolatum base is rapid since they are insoluble in the petrolatum, but readily soluble in tissue fluids. The Ointment is bland and nonirritating.

Caution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: This product is contraindicated in those individuals who have shown hypersensitivity to any of its components.

Supplied: Tubes of 1 oz., ½ oz. with applicator tip, and ⅛ oz. with ophthalmic tip.

Fracture Conference

More Problem Fractures in Children*

Dr. Anthony J. Bianco Jr.:†
Four challenging cases of children's fractures will be presented.

Case 1

Dr. John R. Sebald:‡
This 13-year-old boy was wrestling with his coach in a physical education class as a demonstration when he felt a "snap" in the upper part of his left arm. He came to the emergency room complaining of pain and discomfort on any movement of his arm (Figure 1-A).

Dr. Bianco:
Dr. Santos, what is the mechanism of forces that would produce this kind of injury?

Dr. Ray E. Santos:‡
I think that it is a twist or torsion type of injury.

Dr. Bianco:
It is typical of a torsion fracture—a spiral oblique type of fracture. The alignment of the fracture is reasonably good and there is no vascular injury.

Dr. Santos:
I think a hanging arm cast would do. You might attempt a little more reduction, probably by lowering the position of the arm, which would pull the distal fragment anteriorly.

Dr. Bianco:
If you are going to use a hanging cast, why would you try to reduce it first?

Dr. Santos:
You would not do any actual manipulation, but just try to return the arm to a normal position, and then apply the hanging cast.

---

*Fracture Conference, held at Mayo Clinic, March 25, 1968.

†Assistant Professor of Orthopedic Surgery (University of Minnesota), Rochester, Minnesota. Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester, Minnesota.

‡Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, Minnesota.

Dr. Bianco:

With most boys of this age, it is hard to get them to comprehend the idea of sitting up with a hanging cast and letting it "hang." I think that this patient's mother sometimes put pillows under the boy's elbow because he was uncomfortable. He had a big swollen arm, and in addition his elbow was not really flexed enough. It is hard to get good control of the fracture with the hanging cast at 90° because if the hand drops, there is angulation. You must get the elbow flexed at more than 90°, I think, to get good control of the fragments.

Dr. Sebald:

This was the follow-up film that was taken at six weeks (Figure 1-B). He had been doing well: essentially everything that he did before—like playing the piano. Clinically, the union was solid. We let him wear the collar and cuff for two more weeks, and then these films were taken (Figure 1-C and D).

Dr. Bianco:

There is no angulation, is there?

Dr. Nikolaus D. Langloh:*

No.

---

*Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, Minnesota.

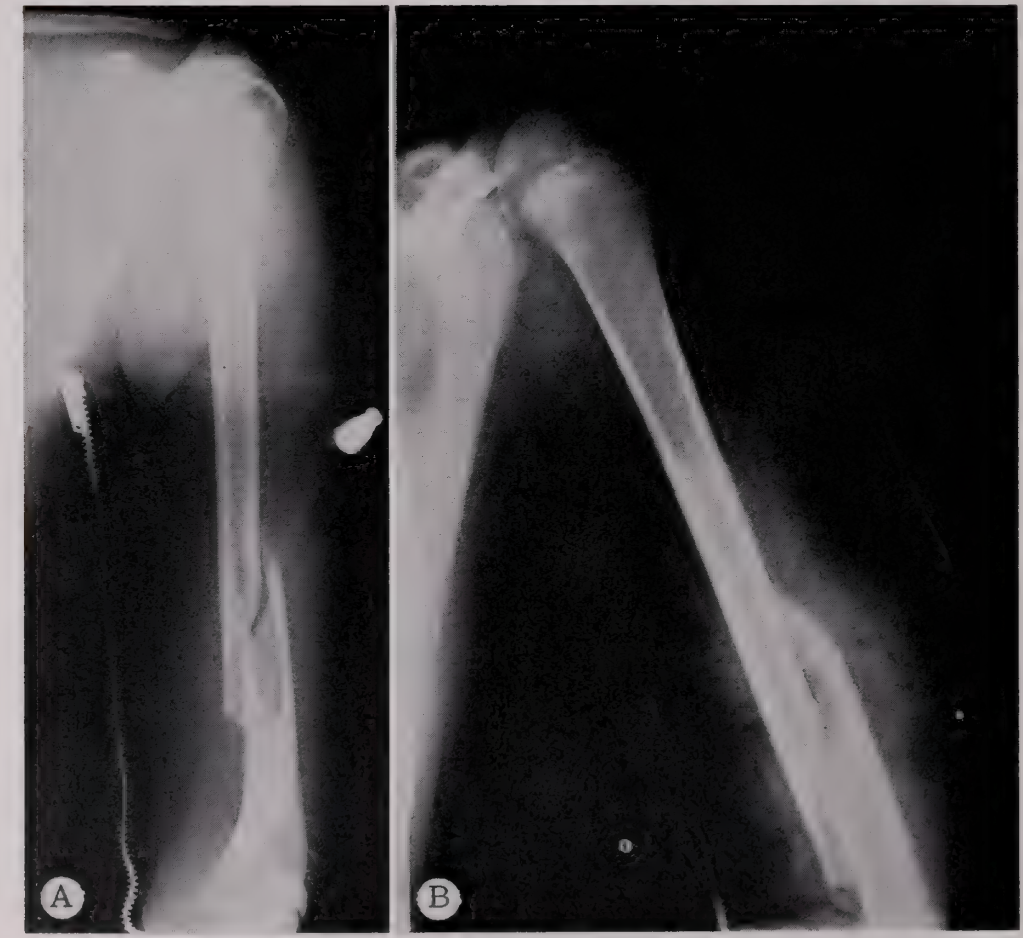

Fig. 1—(Case 1). (A) Spiral fracture of left humerus at junction of mid and distal thirds. (B) Six weeks after fracture, left humerus is in hanging cast.

Dr. Bianco:

Let us look at the films again (Figures 1-C and D). Here is a boy 13 years old. He has some shortening—1 cm or maybe more. His alignment, as you say, is good. I do not think there is angulation in any plane. We checked this carefully. Can we accept that?

Dr. Langloh:

Yes, if there is any shortening it probably will not be noticeable after the first few months.

Dr. Bianco:

First of all, the fracture occurred in the upper extremity. If some minor degree of shortening does result, it will be easy to disguise it. In a boy of this age, normal growth will even up the bones. If this were the femur or tibia of a 13-year-old boy, would you accept this reasoning?

Dr. Langloh:

Yes, I think the fracture itself will stimulate the growth rate so that there will be compensation for any loss of length.

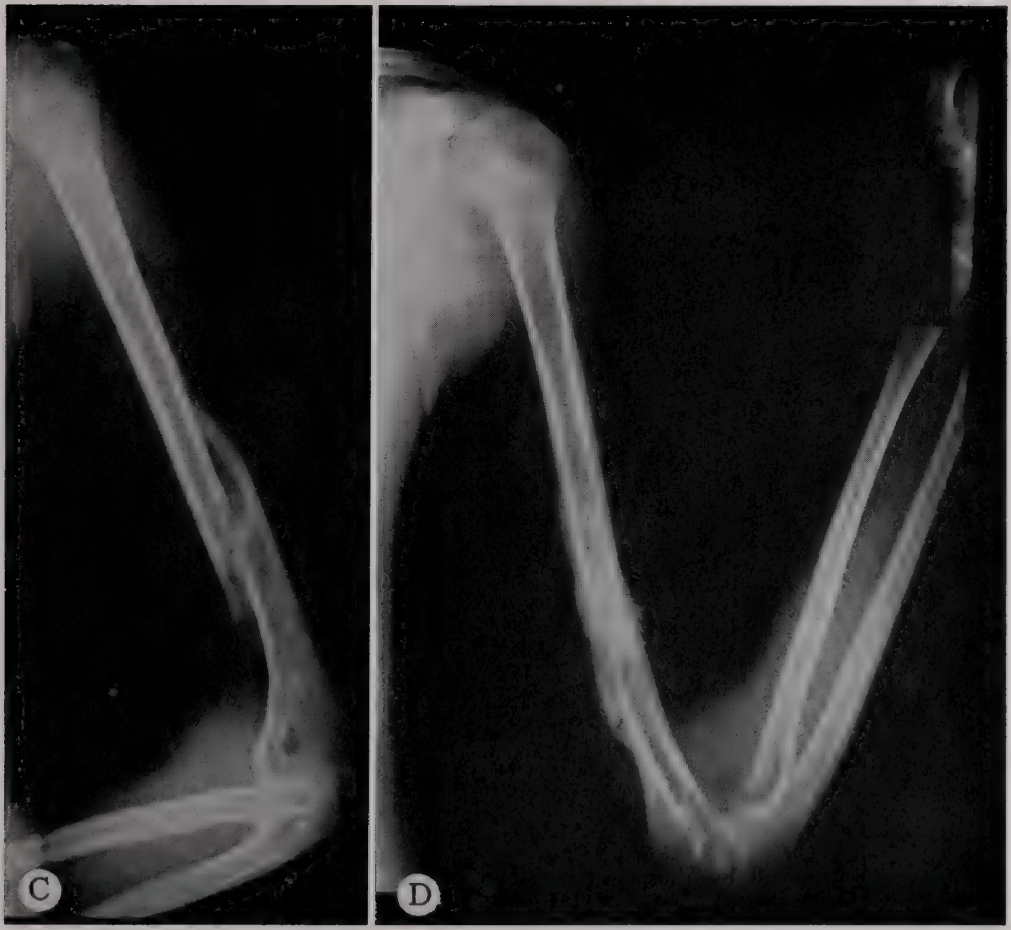

Fig. 1—(Case 1) (C) and (D) Anteroposterior and lateral views two months after fracture. Solid union, with no clinical deformity.

Dr. Bianco:

I agree. I accept this, too. In fact, this is desirable. I think that many have said that if you get an end-to-end reduction in a child this age, you are likely to get overgrowth temporarily. Dr. Johnson, were you going to say something?

Dr. Einer W. Johnson, Jr.:*

I agree with accepting a certain amount of shortening because there is always an increase in growth in a child after fracture of a long bone.

Dr. Richard S. Bryan:†

Just one comment about technique. You can, if you have a patient who is difficult like this one, set up a hanging arm cast, put a hook on the corner of the elbow, hang a three-pound weight off the foot of the bed, and you will get traction on the humerus, even if the mother puts pillows under the elbow.

Dr. Bianco:

This is a good point. The first week that he was in bed he had a tremendous amount of swelling and ecchymosis. During that period, I was not too con-concerned about it because I knew that as soon as he felt well enough, he would want to get up and get going, and he did. Once he got up, the arm did not have good position for the first week or 10 days, but it did not take long before the cast started to "hang." We changed the cast and flexed the elbow a little more and got what we wanted. Now, Dr. Lilly, you asked me something about a radial nerve injury at this time. What would you do?

Dr. Alan D. Lilly:‡

This is why I asked you. I have not made up my mind yet.

Dr. Bianco:

In a boy this age, I would wait and assess the effects of time.

Dr. Lilly:

If you have a radial nerve injury at this time what should be done? I have heard that nerve exploration is recommended.

Dr. Bianco:

I would not do an exploration in a boy of this age at this early stage. I think that most patients will recover if you wait. Now suppose, however, that six or eight weeks have passed and there is no sign of any return of radial nerve function, then I think there may be an argument for examining the nerve. But initially, no. Dr. Peterson, do you agree?

Dr. Hamlet A. Peterson:#

Yes.

Dr. Johnson:

I agree. One other important point concerns the proper splinting of the hand. I would use a dynamic splint or, if a dynamic splint was not available, I would put the wrist, fingers and thumb in hyperextension if there were a radial nerve injury. This is only good common orthopedic judgment, but for completeness we ought to mention that if there is a radial nerve lesion at this stage of injury, you can incorporate the hand splint in a hanging cast. While you are waiting for return of the nerve, the muscles supplied by that nerve should be protected by a proper splint.

---

*Associate Professor of Clinical Orthopedic Surgery (University of Minnesota), Rochester, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

†Assistant Professor of Orthopedic Surgery (University of Minnesota), Rochester, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester, Minnesota.

‡Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, Minnesota.

#Instructor in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, Minnesota, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester, Minnesota.

Dr. Bryan:

I have seen a patient who had the nerve caught at the fracture site and kept getting "electric shocks" distal to the site. This probably is reason for exploration of the nerve without delay.

Dr. Bianco:

The trend in treating patients who have radial nerve injuries and fracture of the humerus or humeral shaft is toward early exposure of the nerve. I am not saying you should just wait and wait indefinitely, but I think that in a child with this sort of fracture, particularly, you should not explore the nerve as your primary treatment but wait six to eight weeks. If there is absolutely no sign of any return of nerve function in six or eight weeks, then you are certainly justified in exploration. But most function returns by itself, I think. Any more questions about this case?

Dr. John H. Shertzer:*

If you explored the left arm now for a nerve lesion, what would you do with the fracture?

Dr. Bianco:

In this instance, if you have a complete radial nerve lesion, you must have stability of the bone on completion of the nerve repair, and I would use either a compression plate or some form of internal fixation—intramedullary nail or something—but probably a compression plate.

Dr. Allen P. Schlein:*

There was an article in the *Journal of Bone and Joint Surgery*† describing 45 of these radial nerve injuries and pointing out that manipulation of these fractures in an adult can damage the nerve.

Dr. Bianco:

If the radial nerve was normal before manipulation but was caught during manipulation, and this could be proved, I think the nerve ought to be explored immediately.

Dr. Johnson:

Another point about a hanging cast concerns obtaining good films. Often the roentgenologist will move the patient's arm away from his body in order to get a good lateral or anteroposterior view. I think a transthoracic, lateral, standing position is a good position in order to get a lateral view of the fracture without disturbing it.

Case 2

Dr. Sebald:

This 12-year-old boy, on December 23, 1967, fell backwards while ice skating, landing on his right arm (Figures 2-A and B).

---

*Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, Minnesota.

†Joseph L. Shaw—J Bone & Joint Surgery 494:899 July, 1967.

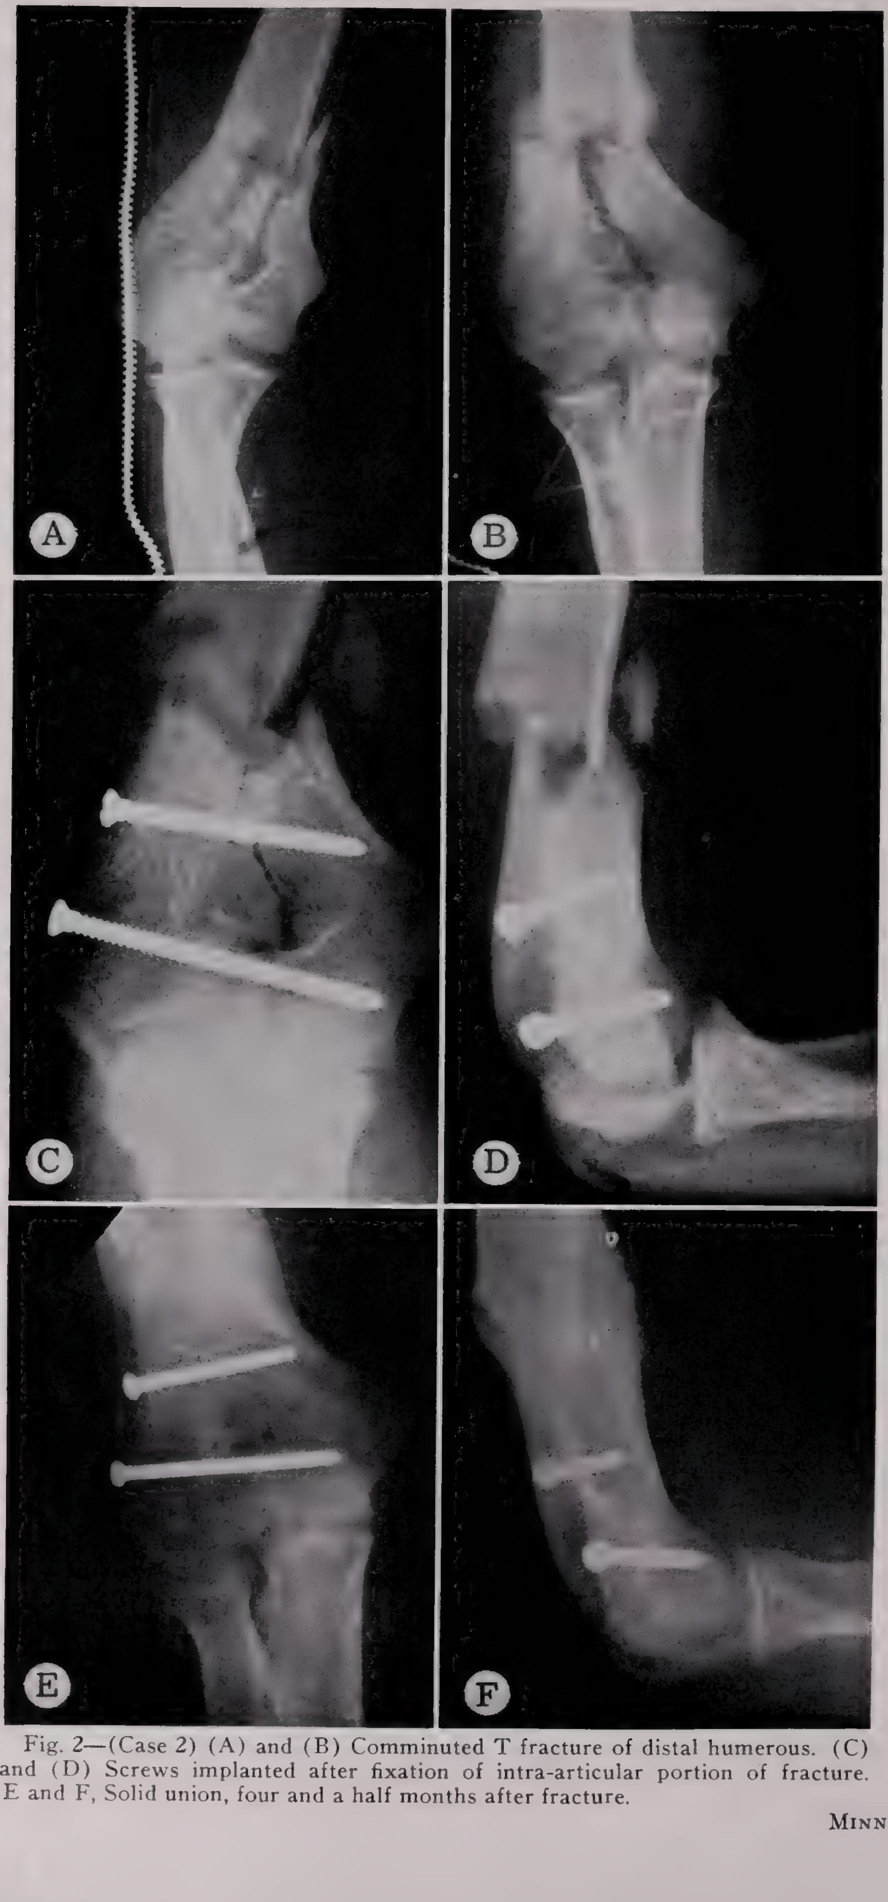

Fig. 2—(Case 2) (A) and (B) Comminuted T fracture of distal humerous. (C) and (D) Screws implanted after fixation of intra-articular portion of fracture. E and F, Solid union, four and a half months after fracture.

Dr. Bianco:

Dr. Chiroff, in a 12-year-old with much swelling but no evidence of vascular or nerve damage, what would you do?

Dr. Richard T. Chiroff:*

I assume that the fracture is not a compound one but a supracondylar fracture with extension to the area between the condyles. It also looks as if there is some rotation of the medial fragment.

Dr. Bianco:

There is an intra-articular component with some displacement.

Dr. Chiroff:

The radial head does not appear to be dislocated. I think closed reduction under general anesthesia would get some compression and molding of these fragments. Then I would put the boy in traction.

Dr. Bianco:

We have been told a lot about how children's bones grow and adapt and remodel, but what do you think about this? If we could get a reasonably good reduction, should we leave it alone and let it take care of itself?

Dr. Chiroff: I doubt whether this would develop into a perfectly normal arm if left as it is.

Dr. Bianco:

The fracture is down into the joint, between two articular areas of the elbow. Maybe we would not need to do anything about it.

Dr. William H. Bickel:†

I do not think the solution is as simple as it might be. There is external rotation of the medial fragment, and every time an articular surface is involved, you need a perfect reduction, if possible.

Dr. Bianco:

That is the point I am trying to make. This is an intra-articular fracture, even though it is between two major joint surfaces, and there is displacement.

Dr. Sebald:

The patient was placed in olecranon skeletal traction, but about four or five days later there was no improvement.

Dr. Bianco:

Why was this fracture not helped by longitudinal traction, Dr. Van Ness?

Dr. Noel T. Van Ness:* Because there was no lateral compression.

Dr. Bianco:

That is right. In other words, the force of displacement is lateral. We put him in traction, more or less, to control the swelling.

Dr. Sebald:

After surgery, a Robert Jones dressing was applied, and approximately one week later the patient was placed in a hanging cast.

---

*Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, Minnesota.

†Professor of Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, Minnesota, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester, Minnesota.

Dr. Bianco:

We have the intra-articular part of this fracture reduced under direct vision and have achieved good position (Figures 2-C and D). Now what about that transverse supracondylar fracture, Dr. Van Ness? Should we have done something about that? Should we put in a compression plate or use a "Y" plate?

Dr. Van Ness:

I do not think either would be necessary. You want to get better alignment of the joint even in a growing child.

Dr. Bianco:

Supposing this were a fracture in the same region but without the intra-articular involvement?

Dr. Van Ness:

You could put a pin through the olecranon. You would get fairly good alignment with this method.

Dr. Bianco:

I think this would be acceptable. Do you think you could handle it with a hanging cast?

Dr. Van Ness: No.

Dr. Bianco:

We put him in a hanging cast. We got the fracture reduced in surgery.

Dr. Sebald:

He was in the hanging cast for five weeks, during which time he had a severe rash under the cast and down the abdominal wall where the cast was rubbing; so we had to remove the cast.

Dr. Bianco:

Six weeks after the fracture, the cast was removed. These films were taken four and a half months after fracture (Figures 2-E and F). Clinically the result was good and the union solid. These films were taken with the arm in flexion because the boy could not extend his elbow. This makes it look as if he has a cubitus varus, which he did not have. His humerus is perfectly straight.

Dr. H. Peterson: When should the screws be removed?

Dr. Bianco:

I would not remove them unless the screw heads cause pressure or irritation. I would leave them where they are.

Dr. Bickel: I agree.

Case 3

Dr. Sebald:

Next is a 13-year-old girl who was turning cartwheels at home and fell on her left elbow, suffering what was probably a valgus strain. She came in with a sore, mildly swollen left elbow. These films were some of several taken in the emergency room (Figures 3-A and B).

Dr. Bianco:
Dr. Fuller, the girl fell while turning cartwheels, had a pain in her elbow, with limited motion. What is wrong?

Dr. Edwin B. Fuller:* The olecranon is dislocated.

Dr. Bianco: Correct!

Dr. Fuller: The left forearm seems to be a bit rotated.

Dr. Bianco: What about the tip of the olecranon in relation to the humerus?

Dr. Fuller:
It is a little lower on the left side, and it could be dislocated. I cannot tell definitely.

Dr. Bianco:
True, but something else is wrong with the way the joint surfaces fit. The olecranon is more distal than it should be. Look at the joint space where that peculiar object is. Compared to the normal other side, the joint surfaces are

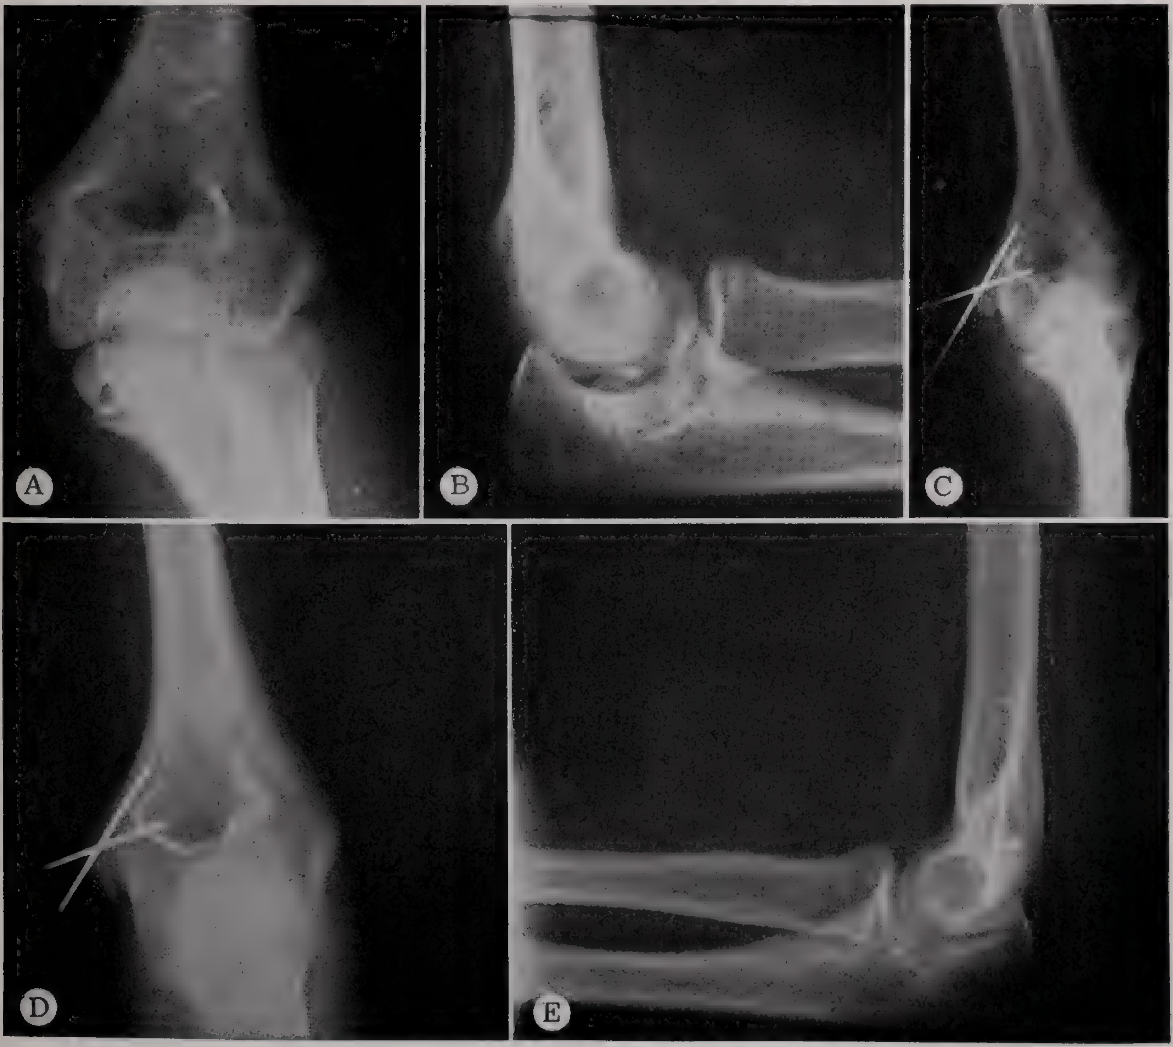

Fig. 3—(Case 3). (A) and (B) Avulsion fracture of medial epicondyle, with entrapment in elbow joint. (C) Operative film, K-wire fixation of medial epicondyle. (D) and (E) Anteroposterior view five weeks after fracture, just prior to removal of Kirschner wires.

parallel in the right elbow; they fit together very well. You say that elbow might be dislocated? What could be dislocated and still look like that? Let us assume, however, that it is dislocated.

Dr. Fuller: It could come from the tip of the olecranon.

Dr. Bianco: What could come from the tip of it?

Dr. Fuller: The fragment in the joint.

Dr. Bianco:
All right, the elbow is dislocated and there is a fragment in the joint. Look at the shape of the distal humerus, as compared to the other side. Look at the whole distal humerus. Something is missing. We have a fracture-dislocation with a fragment in the joint. The question is, where does this fragment come from and how big a piece do you think it is?

Dr. Rogers C. Southall:*
The medial epicondyle. We cannot see how big it is, but it is probably somewhat bigger than shown because of the cartilaginous condyle. It is not unusual for a medial epicondylar fragment to be displaced into the joint.

Dr. Bianco:
Right! My point is that the fragment is usually considerably bigger than this. This type of fracture is sometimes described as a condylar fracture, not an epicondylar fracture. More of the condyle is fractured off. What significance does this fragment have, other than being in the joint? Can you just take the fragment out?

Dr. Southall:
You have to leave the fragment intact. It represents growth of the medial epicondyle.

Dr. Bianco:
I imagine that you could get along without a medial epicondyle if you had to. What is attached to the fragment?

Dr. Southall: The flexors.

Dr. Bianco: The common flexor origin, primarily.

Dr. Sebald:
Because she had eaten recently, we placed her in a Robert Jones dressing with a plaster splint. She was taken to surgery the next day. The joint was approached medially, and it was immediately apparent that this fragment was, as Dr. Southall mentioned, a bit bigger than was apparent on the x-ray, but the common flexor organ was there and attached.

Dr. Bianco:
This was easier to do than I had anticipated. I expected a much bigger fragment. The whole medial side of the joint was obscured by a mass of muscle going into the joint, and once we retracted this common flexor origin out of the way, everything easily fell into place. Fortunately, we found the region where the epicondyle had fractured off, and it fit back very nicely (Figures 3-B and C).

Dr. Sebald:
A Robert Jones dressing was applied for one week, and she was placed in a long-arm cast.

---

*Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, Minnesota.

Dr. Paul R. Lipscomb:* Did you isolate the ulnar nerve? Did you see it?

Dr. Bianco:

No, the fracture was well anterior to it. We looked for it, but it did not seem that we were that much in the groove. The fracture seems to be more anterior.

Dr. Lipscomb:

Always look for the ulnar nerve.

Dr. Bickel:

If the fragment is small, do not try to use a screw.

Dr. Bryan:

If you see such a fragment early, you can often get the fragment from the joint by having the patient tense his flexor muscles.

Dr. Bianco:

That is a good point. I have never tried it. What impressed me was that after we got the fragment from the joint, there were no medial ligaments stabilizing the elbow. Everything on the medial side was ruptured, and even with the fragment out of the joint, you could spring the elbow wide open. There were no other structures stabilizing the medial side of the joint. This is another reason for getting a good anatomic reduction. There is no medical stability of the elbow.

Dr. Bickel:

I do not think you have to worry about the ulnar nerve in a small fracture like this, but the ligaments and the muscles must be repaired. You lose stability if you do not put the condyle back.

Dr. Sebald:

This is the final x-ray just prior to removal of the K wires (Figures 3-D and E).

---

*Professor of Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, Minnesota, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester, Minnesota.

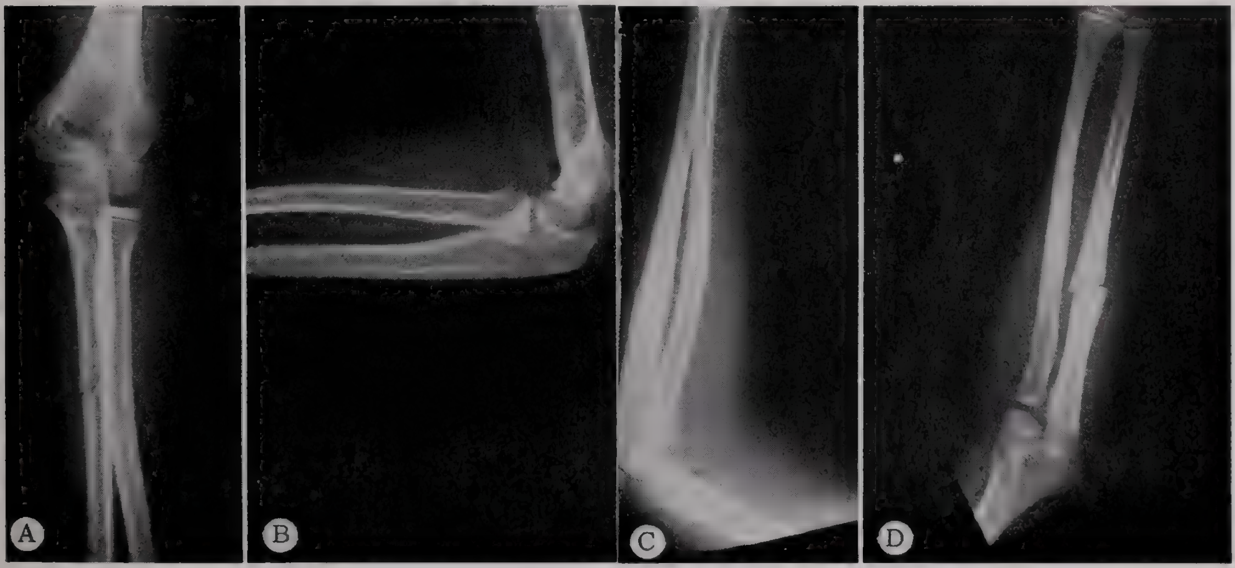

Fig. 4—(Case 4). (A) and (B) Undisplaced fracture of left ulna. (C) and (D) Refracture of left proximal mid ulna 10 weeks after initial fracture.

Case 4

Dr. Sebald:

The next case is of a seven-year-old girl who fell off a swing and landed on her left arm. When she came to the emergency room, she had pain and swelling just distal to the left elbow (Figures 4-A and B).

Dr. Bianco:

Dr. Turner, do you see anything there?

Dr. Richard H. Turner:*

There is an undisplaced disruption of the ulna.

Dr. Bianco:

Do you think we ought to break through the other side of the cortex?

Dr. Turner:

This should be considered because it appears that the fracture is a greenstick fracture of the ulna even though it is without disruption of the cortex. When you have a fracture through one side of the cortex in a child, the other side of the cortex should be broken lest discrepancy in the length and bowing develop in healing.

Dr. Bianco:

I am not entirely convinced there is a fracture of the radius. This may or may not be visible on the initial films (Figure 4 A and B). The fracture is undisplaced. Dr. Peterson, would you consider this?

Dr. H. Peterson: Just immobilize it.

Dr. Bianco:

That is just what I did. The other side of the cortex should be broken when

---

*Resident in Orthopedic Surgery, Mayo Graduate School of Medicine, Rochester, Minnesota.

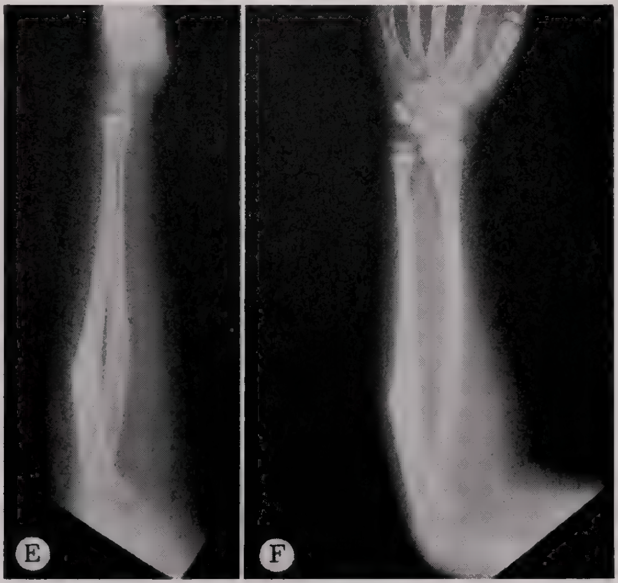

Fig. 4—(Case 4) (E) and (F) Anteroposterior and lateral views 11 weeks after refracture.

you have a greenstick fracture of both bones near the wrist and also have angulation, but this is really an undisplaced fracture.

Dr. Sebald: She was put in a long-arm cast.

Dr. Bianco: Now the question is how long should you hold this fracture?

Dr. Turner: I think that in a child I would hold it about five weeks.

Dr. Bianco: How long did we hold it?

Dr. Sebald: Four weeks.

Dr. Lowell F. A. Peterson:*
One thing was mentioned that I would like to have explained. Dr. Turner, you were worried about crooked overgrowth in the ulna. Is that what you meant to say?

Dr. Turner:
It is my impression that, when you have a fracture through one side of the cortex, the callus formation will hypertrophy that side of the bone and produce a convexity to the side where the fracture was.

Dr. L. Peterson:
You think that the bone increases in length at that side over what it was at the time of the fracture?

Dr. Turner: Yes, that is my impression.

Dr. L. Peterson:
I do not think that happens. Overgrowth is longitudinal at the epiphyseal end, and the angulation you have is not due to an overgrowth.

Dr. Bianco:
The concern with greenstick fractures is primarily the recurrence of the angulation, and I think you have to have some angulation to start with. Do you believe in completing a greenstick fracture for its angulation?

Dr. Bickel:
Most times, yes.

Dr. Bianco:
Considering Volkmann's contracture of the forearm in general, can anyone tell us how many resulted from supracondylar fractures of the humerus and how many resulted from fractures in the forearm?

Dr. Lipscomb:
In the cases we studied a few years ago, about 80% of the fractures were from injury around the elbow rather than in the forearm.

Dr. Bianco:
Here is an undisplaced fracture. So far, everyone agrees that we should put this child in a long-arm cast to hold the fracture.

Dr. Joe L. Nettles:†
Was there any evidence of dislocation of the head of the radius?

Dr. Bianco: No.

Dr. Shertzer:
Did you have an x-ray of the wrist on the initial examination?

---

*Assistant Prfessor of Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, Minnesota, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester, Minnesota.

†Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, Minnesota.

Dr. Sebald:

Yes. She was immobilized four weeks, and then the cast was removed, and she was told to be careful for two weeks. She was seen at that time and was clinically normal, had good motion, no pain, and no discomfort.

Dr. Bianco: Now six weeks have passed without any trouble.

Dr. Sebald:

Ten weeks after the original injury, she was playing at home and bumped her arm—apparently not too great a traumatic incident—and experienced much pain in the same region of the left forearm.

Dr. Bianco:

So all our arguments about completing the fracture were for nothing. She did it herself 10 weeks later (Figures 4-C and D). She had plenty of periosteal new-bone formation there. From everything I had to go on, this fracture was solidly united. Ten weeks after the injury, there was another incident of trauma. From the appearance of the periosteal new-bone formation, you would think this would have broken somewhere else. My only point in bringing this up is that this region of the ulna just does not heal as rapidly as we think. The trauma did not seem to be severe, and yet she suffered a refracture.

Dr. Sebald:

This time, she was put in a long-arm cast for about seven weeks.

Dr. Bianco:

There is much evidence of healing again. How long has it been now?

Dr. Sebald:

This is 11 weeks after the refracture (Figures 4-E and F).

Dr. Bianco: Is she doing all right now?

Dr. Sebald:

Yes, she was seen one more time one month ago. She had complete range of motion and no discomfort.

Dr. Johnson:

Generally, a fracture in the distal forearm with 15° or more of angulation should be manipulated. Is that right?

Dr. Bianco: And is the fracture completed?

Dr. Johnson:

I think that you cannot manipulate a fracture without completing it.

Dr. Bianco:

Sometimes you do not, unfortunately, complete the fracture. Sometimes you just bend the bones out straight again and put them in a cast and you get excellent position, but only one side of the cortex is fractured. And six weeks later, the angulation is right back where it was when the bone was fractured originally. I believe the greenstick fracture should be completed. The non-completed fractures are the ones that result in the bone springing back, even when there is a good cast. I do not see much reason to manipulate or complete a greenstick fracture that is undisplaced. If it is in anatomic position, I do not think you are accomplishing anything by completing the fracture. Fractures that are angulated, are angulated on one side, with the other side intact, and I think these have a tendency to become deformed again.

Conclusions

These cases have illustrated some points in fracture management:

1. Radial nerve lesions in children should be approached conservatively and explored only if the nerve is cut or caught between the bone ends. If function of the nerve does not occur within six to eight weeks, exploration is indicated.
2. Fractures that involve the joint surfaces should be reduced as accurately as possible to forestall degenerative joint changes in later life. And when a bone fragment is "locked" in the joint, surgical removal is mandatory.
3. Angulated greenstick fractures tend to return to their deformed position unless the "intact" cortex is fractured.

Dr. Datnow completed his medical education at the University of the Witwatersrand, Johannesburg, South Africa, in 1962, after which he spent a year at the university as a lecturer in physiology. In 1965 he received a post doctoral fellowship from the National Academy of Science and spent a year in space medical research in California. At the present time he is a resident in pathology at the Mayo Clinic.

The cover photograph was taken on the North Shore of Lake Itasca near the main camp grounds about 8:00 p.m. using Kodachrome II film, 1/60 sec. at f2.8. The camera was a Pentax—single lens reflex 35 mm.

Specialization Versus Coordination*

Though we may deprecate specialization for the problems it may introduce, its growth is essential to the continued practice of medicine. To the extent that it does flourish, there is concomitant need for integration, interpretation and generalization. The value systems, methods and organization of medical education and practice have adapted well to the needs of society for training of specialists but have left largely unsolved the corollary development of equal stature for the integrating function of medicine. We now face the task of interweaving the benefits of specialization into general medical care. Neither the internist nor the general practitioner as presently constituted are equipped to perform optimally this integrating function. A new kind of generalist is required, not just the introduction of general practice into medical education.†

IMPROPER PAGINATION IS
PUBLISHER'S ERROR

Clinical Path Conference

Acute Renal Failure
Hypernephroma in Middle-Aged Woman

Dr. Hugh Edmondson:*

A 60-year-old white female was admitted because of acute renal failure.

Three days before admission the patient had entered the hospital in a small Minnesota community complaining of weakness and diarrhea which had been present for about two weeks. She had been drinking water and boiled skimmed milk for several days before admission, with no improvement. Very little past history was obtained at that time, but she had apparently been in satisfactory health previously. There were no known inherited diseases in her family.

At the time of this initial hospitalization she had a temperature of 100.4°. Blood pressure was not recorded. She was described as dehydrated, fat, and able to speak coherently but weakly. Physical examination of the head, eyes, ears, nose and throat was normal. There were no palpable lymph nodes. The lungs were clear. The heart was of normal size with regular rhythm and normal heart sounds. No murmurs were heard. The abdomen was described as protuberant and obese and no organs were palpable. Pelvic and rectal examination was not performed. A trace of edema was observed in the lower extremities. Neurological examination was normal. Her hemoglobin was 10.9 gm %; white blood count 14,300 with 90% neutrophils. The urine had a specific gravity of 1.026, was negative for albumin, but gave a 3 + test for sugar. Large amounts of yeast were noted in the urine but no white or red blood cells. A chest roentgenogram reportedly revealed an area of consolidation in the right lower lobe.

The following morning her temperature was 102°; respirations were 60 per minute. She was cold, pale and clammy. A thoracentesis was attempted (apparently in the right hemithorax) and 5 cc of bloody fluid were removed. Her blood pressure fell and could be maintained only by intravenous administration of Metaraminol and hydrocortisone. The urine output remained adequate. At this time the blood glucose was 560 mg % (intravenous solutions containing glucose were being administered); serum sodium was 147 mEa/L; potassium 4.7 mEq/L; chloride 96 mEq/L and CO_2 combining power 36 vol % (normal 55 to 75 vol %). The blood urea nitrogen was 45 mg %; hemoglobin 8.6 gm %, white blood count 10,850. Intravenous insulin was administered and she was given transfusions of three units of whole blood.

On the third hospital day her hemoglobin was 12.5 gm %; her white blood count 13,350 with 85% neutrophils; her blood glucose 500 mg %. She was then transferred to a private hospital in Minneapolis. On admission she was hypotensive and required continuous infusions of vasopressive agents including norepinephrine and isoproterenol. Her blood urea nitrogen was 129 mg %; her blood glucose 398 mg %; her serum acetone negative. Serum sodium was 147 mEq/L; potassium 4.8 mEq/L; bicarbonate 27 mEq/L; chloride not recorded. The

BREAK IN PAGINATION IS
PUBLISHER'S ERROR

patient was observed to be oliguric and failed to attain adequate urine output after intravenous administration of 25 grams of mannitol and 50 mg of ethacrynic acid.

Six hours after this admission she was given 0.5 mg Lanoxin intravenously and 50 units of regular insulin subcutaneously, and was transferred to Hennepin County General Hospital.

Physical Examination

On admission the patient appeared to be moribund, was obese, unresponsive and edematous. Her pupils were small, equal and reacted poorly to light. Her mouth contained dried secretions. Respiratory excursions were shallow and symmetrical. Coarse rales were heard over the lower half of both lung fields and breath sounds were poorly audible. The cardiac impulse was barely palpable, but no murmur or gallop rhythm could be heard. The abdomen was described as obese with no palpable organs. Pelvic and rectal examinations were not performed. Extremities were pale and cyanotic. There was minimal response to painful stimuli, but no focal neurological defects were observed. Blood pressure was recorded as 40/0; temperature was 97.2°; pulse 110. The central venous pressure was 4.5 cm of water.

Hospital Course

An endotracheal tube was inserted and respirations were supported with a mechanical ventilator. Blood pressure was maintained with a continuous intravenous infusion of isoproterenol and Levophed. Five percent sodium bicarbonate was administered at a rate of 60 cc per hour. A chest roentgenogram was obtained.

On admission her hemoglobin was 13.4 gm %; white blood count 11,600 (no differential); serum sodium 149 mEq/L; potassium 5.5 mEq/L; chloride 100 mEq/L and bicarbonate 27 mEq/L. Blood glucose was 715 mg %. Fifty units of regular insulin were administered at the time of admission. During the 24 hours after admission the patient remained unresponsive. Her temperature rose to 102° and her urine output was only 20 cc. Twenty-four hours after admission her hemoglobin was 9.6 gm %; hematocrit 28%; platelets were felt to be adequate. Her serum sodium was 151 mEq/L; potassium 6.3 mEq/L; chloride 86 mEq/L and bicarbonate 21 mEq/L. Her prothrombin time was 63 seconds with a normal control; fibrinogen was 126 mg %. Her blood pressure became increasingly unstable and finally imperceptible. She expired. An autopsy was performed.

Clinical Discussion

This is an interesting patient who presented with a brief illness characterized primarily by diarrhea with rapid progression into a state of hypotension and shock. In reviewing the protocol, there are certain points that are important for our discussion. Apparently she had been in good health prior to the onset of this illness, with no evidence of chronic disease. Her family history was noncontributory. It is significant that her primary examination in the first hospital was remarkably normal except for dehydration and weakness. A low-grade fever and a trace of edema were noted. She had no evidence of disease in the gastrointestinal tract at this time. Important laboratory data include a significant leucocytosis with a left shift, glycosuria, anemia of 10.9 gm%, and a chest x-ray revealing an area of possible consolidation in the right lower lobe. It is also significant that her temperature rose to 102° the following morning.

At this time she developed clinical shock and remained in shock apparently for the remainder of her four days of life. Her initial blood sugar was elevated at 560 mg% and her CO_2 combining power was slightly decreased. After transfusion the hemoglobin rose to 12.5 gm% and she was transferred to another hospital in this area. At the time of transfer here she was still hypotensive; her blood urea nitrogen was 129 mg%, blood glucose 398 mg% and her serum acetone negative. Electrolytes at this time were within normal range. This is the first mention that we have of low urine output. Mannitol and ethacrynic acid failed to improve urine output. Because of the persistent oliguria, she was transferred to Hennepin County General Hospital for treatment of her renal failure.

At the time she arrived at this hospital she was moribund, dehydrated, unresponsive, and showed signs of respiratory distress. Quite significantly, the abdominal examination again was apparently unremarkable except for obesity. In spite of heroic measures at this hospital with supported respirations via a mechanical ventilator, continuous infusion with isoprel and Levophed and intravenous therapy, she expired within 24 hours. Significant laboratory data on this final admission revealed a relatively normal white count of 11,000, essentially normal electrolytes, and a markedly elevated blood glucose of 715 mg%. It was only terminally that the electrolytes were noted to be somewhat abnormal. At this time her serum sodium was 151 mEq/L and potassium 6.3 mEq/L. Two other laboratory values of significance terminally were a prothrombin time of 63 seconds and a fibrinogen of 126 mg%.

We might begin our discussion of the differential diagnosis by considering the pulmonary problem. I don't believe this was a major cause of her illness, but nevertheless she did present with a right lower lobe consolidation, rales, fever and respiratory distress. Could we see the x-rays now, please?

Dr. Oscar Lipschultz:*

The films that we have taken at this hospital are inadequate for interpretation. These are supine films. There is a haziness in the right lower lobe, and whether this represents a distinct consolidation or not is difficult to determine. We do not have the x-ray films from the other hospitals.

Dr. Edmondson:

Interpretation then of the x-rays are that they are not much help at all. Is that correct?

Dr. Lipschultz:

That is correct.

Dr. Edmondson:

With a patient who presents with pulmonary consolidation and bloody pleural fluid, we have to consider an infectious process and pulmonary emboli. However, I do not think we have enough evidence to establish a clear diagnosis in this area or to distinguish between these two possibilities. One must also consider a dissection of an aortic aneurysm in a patient who has such a rapid demise.

Let us now consider the gastrointestinal aspect of her disease. Her one complaint on admission was diarrhea. It is worthwhile at this time to review the etiology of this complaint. Diabetes needs to be strongly considered in this lady because she was elderly and obese and had a persistently elevated blood sugar. Diabetics certainly can have recurrent episodes of diarrhea. This presumably is due to the diabetic effects on the nerve supply to the gut. This usually is an intermittent type of diarrhea which rarely is severe enough to cause dehydration to this extent and certainly would be unlikely to produce a state of shock. It is not clear to me whether she did have diabetes; but I don't believe this was her underlying problem. The second possibility that needs to be strongly considered in such a rapid downhill course is a mesenteric vascular catastrophe. An elderly, obese, possibly diabetic lady would certainly be a good candidate for mesenteric vascular insufficiency. However, the fact that she had no evidence of vascular disease in other areas tends to rule against this possibility. These patients usually present with a history of abdominal pain, usually following meals, and weight loss. Frequently this condition will lead to an audible bruit in the upper abdomen.

---

*Staff Radiologist, Hennepin County General Hospital.

Other causes of diarrhea would include the various inflammatory diseases of the small and large intestines. Elderly patients certainly can present with fulminant regional enteritis or ulcerative colitis. The fact that she did not have a bloody diarrhea would tend to rule out ulcerative colitis. The absence of a previous history of gastrointestinal complaints also would tend to exclude these disease entities. The possibility of bacterial or parasitic infections also exists. However, without stool studies or cultures, it would be pure guess work to implicate a specific etiologic agent. We also lack the benefit of a rectal examination or a barium enema.

The possibility of peptic ulcer with its complications should be considered, but against this is the lack of a previous history suggesting peptic disease. Also, after two weeks of diarrhea, she showed no evidence that she was hemorrhaging into the gastrointestinal tract. Therefore, I think a bleeding peptic ulcer would be unlikely. However, a perforated peptic ulcer can certainly be present in the older age group with rapid progression to peritonitis and shock, but the absence of abdominal tenderness or signs of a surgical abdomen would tend to rule against this diagnosis.

I believe the gallbladder area sounds more promising. An elderly, obese, possibly diabetic lady would be a prime candidate for gallstones. Complications of gallstones that need to be considered are an acute cholecystitis with perforation of the gallbladder or an acute ascending cholangitis with development of multiple hepatic abscesses. But the absence of a good history makes these diagnoses tenuous. Lack of an enlarging liver or a tender liver or jaundice tends to rule against ascending cholangitis with liver abscesses. The absence of abdominal pain, vomiting and tenderness in the upper abdomen would tend to rule against the diagnosis of pancreatitis; also, constipation would be more in keeping with pancreatitis rather than diarrhea. The absence of pain and abdominal tenderness, however, does not completely exclude pancreatitis. Painless pancreatitis may occur.

Perhaps a review of some of her other abnormal clinical findings will give us a clue to the underlying disease. She apparently was febrile on first examination and remained febrile throughout her course. This, of course, would be perfectly consistent with a lobar pneumonia. However, it would also be consistent with any inflammatory disease below the diaphragm. She also was anemic throughout her course, a fact which remained a main stumbling block in establishing a diagnosis. The initial hemoglobin was 10.9 gm%, but this probably was not an accurate estimate of her blood volume because of her initial dehydration. The hemoglobin of 8.6 gm% after administration of intravenous fluids is probably a more accurate value. The fact that she dropped from a hemoglobin of 13.4 gm% to a hemoblogin of 9.6 gm% in less than 24 hours after arrival at this hospital would certainly suggest the possibility that she was hemorrhaging, most likely in the abdomen. I do not believe there is enough evidence on x-ray to suggest that she had a massive hemorrhage into the thoracic cavity to explain the blood loss. The lack of documentation of gastrointestinal bleeding is disturbing. The stools are not described. This might suggest that the blood was lost in an area that was not directly communicating with the gastrointestinal tract. The persistent azotemia, I believe, is just a manifestation of the persistent shock state. She arrived with a BUN of 45 mg%, and this rose to over 100 mg%. I believe this represents a prerenal azotemia. I do not believe we have to implicate acute or chronic renal disease.

Now, is it possible to tie all this information together and explain it on the basis of one disease? I believe the one which would best explain much of her course would be a disease of the pancreas. Patients that present with an acute hemorrhagic pancreatitis can have a speedy course with shock and rapid demise. I think the fact that she was weak and lethargic at the time of her initial presentation and had had symptoms for several weeks might explain the failure to obtain a history suggestive of pancreatitis, such as abdominal pain, nausea and vomiting. One might also have expected to be able to elicit some tenderness in her abdomen on initial examination; however, it is well known that abdominal examinations in elderly, obese individuals can often be misleading.

Hemorrhagic pancreatitis could readily explain the anemia. It is known that patients with hemorrhagic pancreatitis can have rapid loss of blood into the necrotic tissue. The persistently elevated blood sugars would easily be explained on this basis as well. Again, it depends on how much of the pancreas is involved; but it is known that many patients with acute pancreatitis initially have elevated blood sugars. I do not believe that she can be considered a straightforward diabetic because, in spite of these extremely elevated blood sugars, she showed no evidence of ketoacidosis. The changes noted in the blood clotting system in the terminal admission are also consistent with acute pancreatitis. For some reason, patients with acute pancreatitis may have alterations in their clotting factors, and the prolonged prothrombin time and the lowered fibrinogen level would be compatible with this.

I think for the sake of completion we should consider an acute vascular catastrophe involving the mesenteric vessels or the abdominal aorta. This condition would explain the shock-like state, the anemia, and her rapid deterioration. The possibilities of myocardial infarction and vascular abnormalities in other areas probably do not apply in this case.

In summary then, I think this elderly lady had acute hemorrhagic pancreatitis with rapid deterioration. She may have had gallbladder disease as the initial cause of the pancreatitis. Gallstones and stones of the common duct may well be found at autopsy. She may or may not have diabetes.

Dr. Andrew Edin:*

How often when you have a case of hemorrhagic pancreatitis do you see findings in the chest?

Dr. Edmondson:

This can occur. Pneumonia, atelectasis, and bloody pleural effusion have all been described. These, however, are usually present in the left chest, and this patient presented with right-sided findings.

Dr. Robert Strom:†

Would you comment on the amylase levels in renal failure and also on the hemoglobin concentration in acute interstitial pancreatitis vs. that in acute hemorrhagic pancreatitis.

Dr. Edmondson:

We do not have amylase studies available; perhaps they were not done.

---

*Senior Medical Resident, Hennepin County General Hospital.

†Associate Pathologist, Hennepin County General Hospital.

I think when the patient arrived at this hospital in her moribund state, the damage to the pancreas may have been so severe that normal amylase levels might have been obtained. In acute interstitial pancreatitis there is usually an elevation of amylase values; but in the severe hemorrhagic pancreatitis one might not get elevations. In regard to the hemoglobin levels, I can only guess bleeding was probably the main manifestation of her problem. Perhaps if she had been seen a week earlier in her illness, evidence of hemoconcentration might have been present. It is a little hard to explain this extreme anemia and particularly the rapid drop in hemoglobin that was observed in the last day of her life by bleeding into the pancreatic area alone. Perhaps she did have some other complication in the abdominal area which led to bleeding.

Dr. Fred Shapiro:*

We see very rapid development of anemia in acute renal failure, and this factor may have been contributory to her anemia.

Dr. Edmondson:

Do you think a BUN of over 100 is adequate explanation for dropping her hemoglobin almost 4 gm% in 24 hours?

Dr. Shapiro:

I think in situations like this there is a marked hypersplenic effect leading to increased destruction along with the marrow suppression.

Dr. Edin:

Will you comment on the amylase levels in patients with renal failure who do not have pancreatitis?

Dr. Shapiro:

These levels can be extremely variable. In general, they tend to be normal. We never have seen any patients with amylase levels over 500 who are in acute renal failure. Sometimes they will be elevated to 300 or 400, however.

Dr. Strom:

It should be borne in mind that amylase levels in pancreatitis can be often elevated in abnormal collections of fluid, for example, in the pleural space and the pericardial cavity. Determining amylase levels on these fluids can often be of extreme diagnostic importance.

Dr. Edmondson:

This also can be applied to fluid obtained by needle aspiration of the peritoneal cavity as well.

Pathology Discussion

Dr. John Crosson:†

The external examination of the body revealed marked obesity and numerous ecchymoses over all extremities. This probably was a manifestation of the bleeding tendency to which Dr. Edmondson alluded. She also had pronounced xanthelasma of her upper eyelids. When the abdomen was opened, extensive fat necrosis involving all the peritoneal surfaces was seen, both in the upper abdomen and also in the pelvis. There was a small amount of dark fluid present in the abdominal cavity. In the upper abdominal cavity, there was extensive necrosis involving the entire region occupied by the pancreas. Numerous tiny green-grey stones measuring from 1 to 2 mm in diameter were found in the gallbladder. When the common bile duct was probed, many of these tiny stones were pushed through the Ampulla of Vater into the duodenum.

---

*Staff, Department of Internal Medicine, Hennepin County General Hospital.

†Resident, Department of Pathology, Hennepin County General Hospital, Minneapolis.

Figure 1 shows a picture of the common duct opening into the duodenum. The grey tissue around the common duct represents the necrotic pancreas. The pancreatic duct opened directly into the common bile duct 4 mm proximal to the Ampulla of Vater. Therefore there was a common channel measuring 4 mm which drained both the pancreatic secretions and the bile. The pancreatic duct was traced into the pancreas and then suddenly was lost 6 cm from the Ampulla in the necrotic substance of the body and tail of the pancreas.

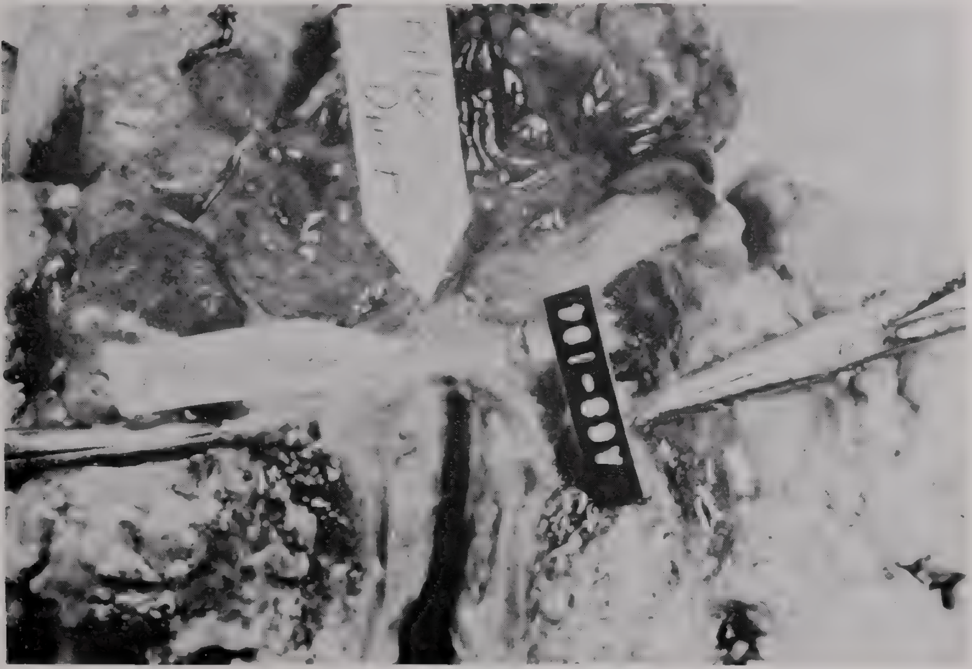

Fig. 1—Acute Pancreatitis

Figure 2 shows viable pancreatic tissue at one corner with marked acinar dilatation. There is also marked edema of the interstitial areas. The rest of the picture shows necrotic tissue and some hemorrhage. The necrotic tissue cannot be recognized as pancreas. There is a very sharp demarcation between the viable pancreatic tissue and the necrotic tissue. This very sharp demarcation, which is characteristic of pancreatitis, has suggested to some authors that much of the necrosis in pancreatitis might be due to vascular insufficiency. Some hemorrhage was observed in the area of necrosis, but this was not prominent. In some areas of fat necrosis in the peritoneal cavity, evidence of calcium deposition was seen microscopically.

The kidneys showed some very remarkable changes on cut section. They appeared enlarged and weighed about 140 grams each. The parenchyma of the kidney bulged somewhat above the cut surface. The cortices were extremely pale, as shown in Figure 3. Besides the changes in the cortex, this picture shows that the right kidney also contained another lesion. Arising from the upper pole of this kidney there was a cystic, yellowish, somewhat hemorrhagic lesion measuring 3½ x 2 cm, which projected towards the hilus of the kidney. Microscopic examination of this lesion showed a typical appearance of hypernephroma with large clear cells containing abundant cytoplasm and small eccentrically placed nuclei. In many areas these clear cells appeared to form glands, and this accounts for the large cystic areas seen grossly. Microscopic examination of the rest of the kidney showed patchy areas of necrosis of tubular epithelial cells. These cells did not, however, show marked vacuolization similar to that seen with Mannitol administration.

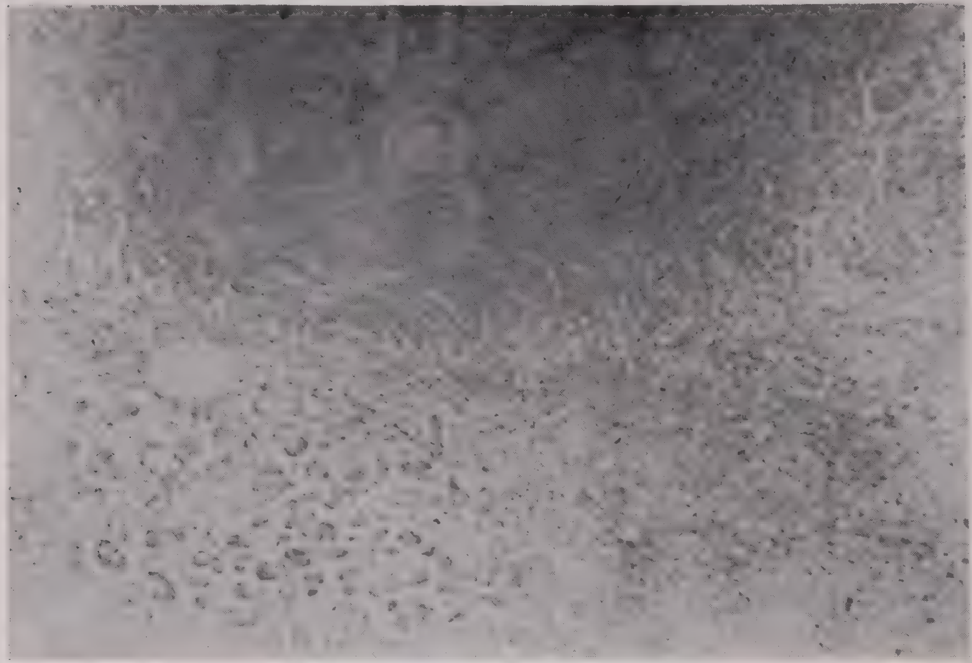

Fig. 2—Necrotizing Pancreatitis

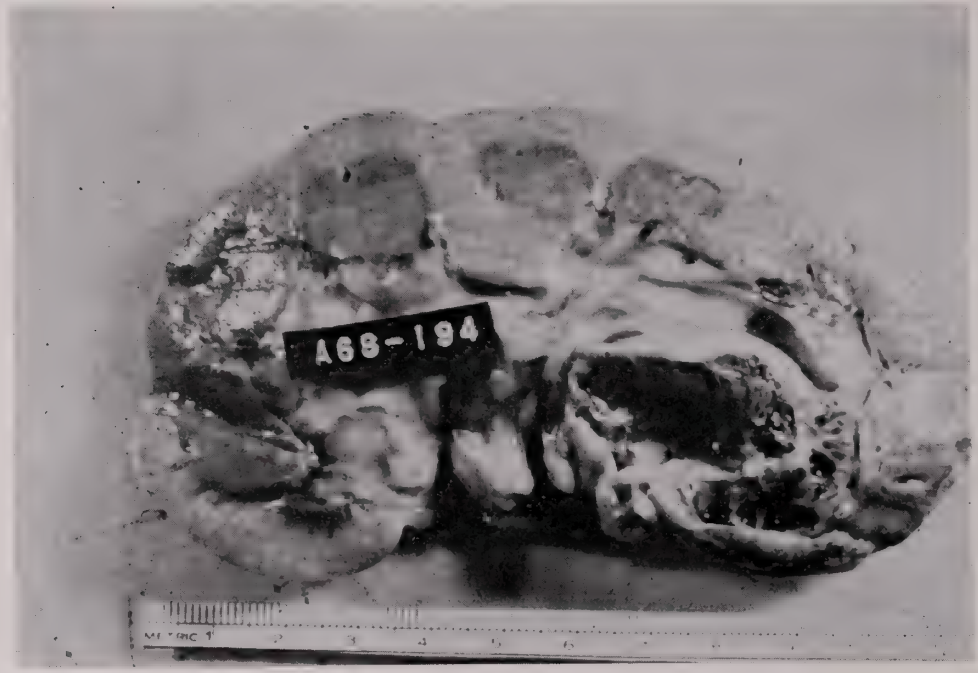

Fig. 3—Hypernephroma

Figure 4 shows a high-power view of several of the tubules which contain necrotic cells in the lumen. One tubule also shows the tubulorrhexic lesion that has been described by Oliver.[1] This consists of a disruption of the basement membrane of the tubule with loss of the contents of the tubule into the interstitial space. This is the lesion that is supposed to be characteristic of ischemic injury in contrast to the nephrotoxic lesion due to chemical injury in which the basement membrane remains intact. Other microscopic sections of the kidney show rather striking areas of interstitial edema without much evidence of inflammatory response. The glomeruli, arteries and arterioles appeared perfectly normal microscopically and showed no evidence of preexisting renal disease. In particular, there was no evidence of diabetic glomerulosclerosis. In reference to diabetes, it might also be mentioned that a few islets were found in the sections of pancreas, but these islets appeared perfectly normal and showed no evidence of hyalinization such as is seen in diabetes.

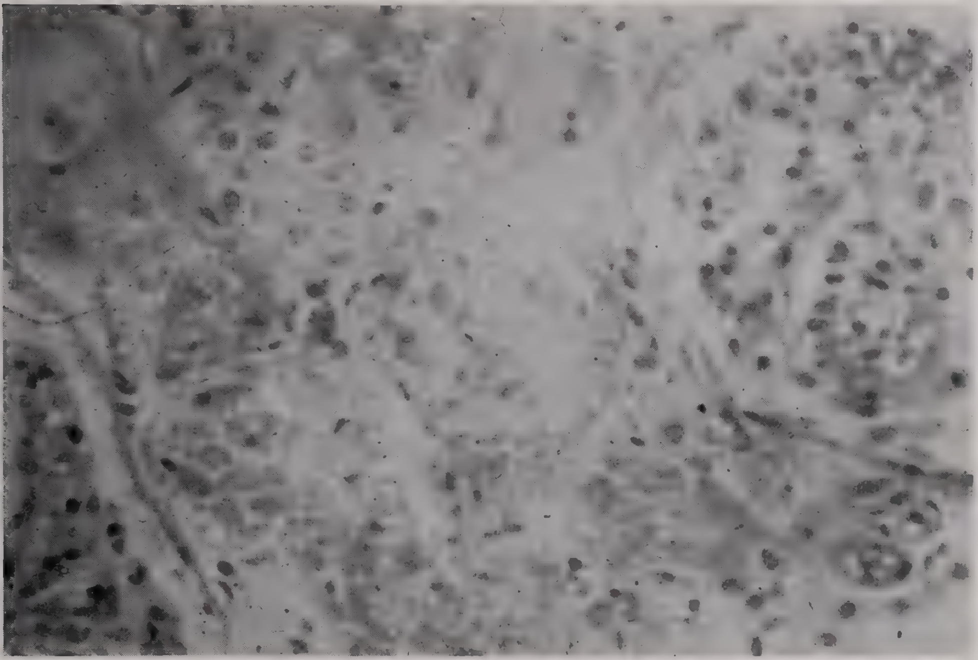

Fig. 4—Tubulorrhexis

The sections of liver showed extensive centrilobular necrosis. When the gastrointestinal tract was opened, large amounts of blood were present within the stomach, esophagus and duodenum, extending well into the small intestine. The stomach mucosa contained numerous small punctate ulcers. Microscopic examination of these ulcers showed them to be quite superficial, extending through the submucosa to the inner muscular layer but no further.

In the lungs, a 1 x 1.7-cm firm, hard nodule was present in the apical segment of the left lower lobe. On cut section this was somewhat elevated above the surface of the lung and was very white in appearance. Microscopic examination of this lesion revealed typical mature hyaline cartilage sharply demarcated from the surrounding lung. This was a typical benign hamartoma. There was also a 5-mm in diameter firm nodule present in the posterior aspect of the upper lobe of the left lung; there were also numerous tiny nodules present throughout the spleen. Microscopic examination of these lesions revealed partially calcified granulomata with only a few giant cells.

Special stains did not reveal any definite organisms, but these lesions certainly would be compatible with healed histoplasmosis. There was extensive bronchopneumonia present in the right lower lobe as well.

In the heart there was evidence of hemorrhage into one of the leaflets of the tricuspid valve; this was confirmed microscopically. There were also numerous punctate hemorrhages throughout the myocardium. Microscopically, these showed evidence of excessive amounts of red blood cells lying between the myofibrils without any significant surrounding inflammatory reaction. There was also gross and microscopic evidence of hemorrhage of the endometrium. The parathyroids were examined carefully and all appeared normal.

A recent article by Block and Priest[2] emphasizes that recurrent pancreatitis can be associated with multiple very small stones in the gallbladder. In their series, these stones were frequently too small to be seen radiographically. At the time of surgery these stones measured 1 to 2 mm in diameter. After removing the gallbladder with the stones, the patients had no further bouts of relapsing pancreatitis. Three of their five patients had definite choledocholithiasis. Stones in the biliary tract are often seen in cases with pancreatitis. In Blumenthal and Probstein's series, 10% of their cases had definite obstructive disease of the biliary tract. They emphasize in their classic monograph[3] that the opening of the duct of Wirsung must be at least 2 to 3 mm above the Ampulla of Vater to permit impaction of a small stone in the ampule without actually occluding the pancreatic duct. This situation was present in this case with the duct of Wirsung opening 4 mm above the Ampulla of Vater.

In their series of acute pancreatitis, about 60% of these cases were associated with antecedent evidence of chronic disease in the biliary tract. It has been shown experimentally that pancreatitis will result when a combination of bile and pancreatic juice is injected into the pancreatic duct. However, for hemorrhagic pancreatitis to be present, vascular occlusion also needs to be present. As mentioned earlier, the sharply demarcated areas of necrosis in this case might suggest a vascular role as well. A logical mechanism for this vascular occlusion would be production of thrombi in the smaller vessels supplying areas of the pancreas. This may be due partly to inflammatory reaction in the vessels and also partly to a hypercoagulable state which has been associated with pancreatitis.

In 1965, Nudelman and co-workers[4] showed that infusion of a bile and trypsin combination into the pancreatic duct in dogs produced an acute pancreatitis, whereas bile alone did not. They also further showed by the use of electron microscopy that a very early lesion produced by the bile-trypsin combination was the loss of micro-villi from the luminal surface of the acinar epithelial cells. As a result, foreign particles were readily ingested into the cells, whereas with micro-villi intact, the cells did not ingest foreign material.

There is one other possible etiology for the pancreatitis that might have existed in this lady. She did have very distinct xanthalasma. There have been cases of recurrent acute pancreatitis reported in patients who have significant hyperlipemia. In these cases, fat emboli may be the etiology. There were no lipid studies performed on this patient.

The association of acute tubular necrosis with acute pancreatitis has only recently been well appreciated. Taylor[5] in 1949 published 110 cases of acute pancreatitis and in only one of his patients was oliguria mentioned. However, in recent years there have been increasing reports in the literature indicating the not uncommon association of these two conditions. In 1962, Balslov[6] reported on 300 cases of acute renal failure in Denmark, 13 of which were due to acute pancreatitis. In 1959 there was a report by Beisel and co-workers of four cases of acute pancreatitis which developed acute renal failure.[7] In three of these, acute tubular necrosis was found; in one the renal failure was due to bilateral renal cortical necrosis.

It is emphasized in this article and in many others that the combination of acute pancreatitis and acute tubular necrosis is a particularly lethal combination. There is an 80% mortality associated with this combination in the literature. The mechanism for the development of acute tubular necrosis is probably the decreased renal profusion secondary to the shock that is present early in the disease. However, Lee and Hills[8] have recently reviewed evidence showing that the acute tubular necrosis is due to a release of some substance from the pancreas into the circulation. Other authors have implicated vasodilator substances, such as bradykinin in these situations.[9] There are other causes of acute renal failure in pancreatitis that have been reported. These are quite rare but probably should be mentioned. One is bilateral renal artery thrombosis; a second is fat emboli to the kidneys from areas of fat necrosis.

The nature of this patient's hemorrhagic diathesis is a bit difficult to elucidate. Reports in the literature vary markedly from a hypercoagulable state to a hypocoagulable state associated with acute pancreatitis. In 1963, Shinowara[10] demonstrated hyperfibrinogenemia and elevated Factor 8 concentrations in cases of acute pancreatitis. However, one has to be cautious in interpreting these elevated levels as being indicative of a hypercoagulable state. Wessler[11] has recently shown that it is important to know whether clotting factors are in an inactive or active form before one can say that a hypercoagulable state exists. It is known that trypsin activates conversion of prothrombin to thrombin, and this rapid conversion could conceivably lead to a hypercoagulable state.

Innerfield,[12] in 1951, found elevated antithrombin levels in 50 of 55 cases of acute pancreatitis. This would support the view that excess prothrombin was being converted to thrombin. It is also known that prothrombin times are often quite prolonged in acute pancreatitis. It thus seems quite likely that early in the course of pancreatitis a hypercoagulable state might exist, perhaps secondary to trypsin release into the circulation and its subsequent action on the prothrombin. As clotting factors are used up later in the course of the disease, a hypocoagulable state might readily exist: in other words, a consumption coagulopathy. This patient's prolonged prothrombin time and decreased fibrinogen terminally would substantiate this. Her prothrombin time could also have been prolonged secondary to the extensive centrilobular necrosis that was present in the liver.

Summary

The case is that of a middle-aged, obese woman who had numerous small gallstones present in the gallbladder, several of them in the common duct. She had a common drainage channel measuring 4 cm for the pancreatic secretions and the bile. Secondary to these findings, she developed a severe hemorrhagic and necrotizing pancreatitis. As a result of this hemorrhagic pancreatitis, she developed acute tubular necrosis and went into renal shutdown. She had numerous small gastric ulcers which led to massive

gastrointestinal hemorrhage and would account for the rapid terminal fall in hemoglobin.

There were also several interesting incidental findings: a hypernephroma of the right kidney; a hamartoma in the left lung; probable healed histoplasmosis involving the left lung and spleen; a bleeding diathesis which manifested itself by multiple skin ecchymoses, hemorrhage into the myocardium, and possibly hemorrhage into the tricuspid valve.

Dr. Shapiro:

Are these ulcers in the stomach the kind that you can see in patients who receive large amounts of Levophed?

Dr. Crosson:

We attributed the presence of the ulcers to her uremic state. I think Levophed might well have contributed, however.

Tourniquet Paralysis Syndrome

Mechanical pressure from a tourniquet may cause both motor and sensory changes in the function of peripheral nerves. According to Moldaver, muscle paralysis may be present with either hypotonia or atonia although there is no evidence of atrophy. Sensory dissociation also occurs. The sensations of touch, pressure, vibration, and position are usually absent. Duration of impairment of both the sensory disturbance and motor function may be as long as three months or more.

Case Reports

Drug Fever Due to Procainamide

SINCE LEIBOWITZ in 1951[1] first described fever after the use of procainamide, a few more similar cases have been reported. They all resemble each other more or less, but the importance of *primum nil nocere* justifies the description of another case.

Case Report

History

A 64-year-old white man was admitted to Northwestern Hospital on April 12, 1968, because of chills, fever, headaches and muscular aching of two days' duration.

He had previously been admitted to the same hospital on March 24, and remained until April 6 of that same year with a complaint of dyspnea that he described as "choking and inability to get air." He stated that he had had a number of similar attacks over the preceding ten years. His history included hospitalization 27 years before for a "nervous breakdown." Other hospital admissions were for a tonsillectomy, hemorrhoidectomy, rectal fistula and herniorrhaphy years before. The patient also complained of life-long migraine headaches and sinus trouble.

Physical examination revealed a few moist crepitant râles in both lung bases and slight cardiac enlargement. A late blowing systolic murmur was heard best at the apex, with a muffled second sound (S_2). (A systolic murmur was first noted by his physician* in 1963). An electrocardiogram showed multifocal ventricular premature contractions and ST-T wave changes compatible with left ventricular ischemia. His circulation time arm to tongue was 22 and 19.5 seconds. All these findings suggested that he might have slight mitral incompetence, possibly due to a dysfunction of the posterior papillary muscle. Bronchoscopy performed on April 4, 1968, revealed a laryngospasm associated with chronic bronchitis. The patient was digitalized and given Pronestyl® (procainamide) 250 mg. four times daily and Valium® 5 mg. three times daily; these were commenced on March 25, 1968, and continued on discharge, April 6, 1968. At this time there were no premature ventricular contractions.

Physical Examination

On this second admission, April 12, 1968, the blood pressure was 132/74 mm. Hg., temperature 104° F., pulse 96/minute. The patient was shivering and having chills. There were moist crepitant râles in the left lung base. A grade III/VI late blowing systolic murmur was again heard best at the apex. There was no evidence of jaundice, adenopathy, enlarged liver or spleen, rash or petechiae. Examination of the joints showed no abnormalities.

Laboratory Data

The erythrocyte sedimentation rate was 28 mm. in the first hour; hemoglobin 14.8 g%; white blood cell count 8,000 cells/mm^3 with the following hemogram: 75% polymorphonuclear cells, 19% lymphocytes, 2% myelocytes, 3% eosinophils and 1% basophils. The prothrombin time was 14.2 seconds (control 12.7 sec.). The platelet count was 267,000/mm^3, and 1.4% reticulocytes. A lupus erythematosus clot test was negative on two occasions. Determinations of serum electrolytes and enzymes, including amylase, were within normal limits. On examination of blood from the ear lobe, no histiocytes were seen. Complement fixation tests were negative for histoplasmosis, blastomycosis, and coccidiomycosis. Serum total protein was 5.8 g% (3.3 g% albumin and 2.5 g% globulin). The serum bilirubin level was 0.1/0.6 mg%, the blood urea nitrogen 17 mg%, the uric acid 3.6 mg%. Urinalysis was negative; two of the 10 urine cultures grew out E. coli about 100,000/cc. Stool examinations showed occult blood trace to 2+. Serology was negative for paratyphoid A and B, Brucella, and Weil Felix Ox19. Blood cultures for aerobic and anaerobic organisms, as well as for fungi, were negative. Fluorescent antinuclear antibodies were not found. X-ray studies included the skull, an intravenous pyelogram, a cholecystogram, and the chest; no abnormalities were seen. An examination of the bone marrow proved normal. The spinal fluid contained no white or red blood cells; 83 mg% sugar; Pandy was negative. Electrocardiographic tracings showed atrial premature beats but no premature ventricular contractions.

---

*We wish to thank Dr. Lyman Clay for referring this interesting case.

Course

The patient's temperature ranged from 99.2 to 104.5° F. for the first four days after his admission. During that time he was given 250 mg. procainamide four times daily, Valium® 5 mg. three times daily, and on seven occasions 650 mg. aspirin (ASA). After all medications were discontinued on the evening of April 15, the temperature returned to normal on the evening of April 16 and remained normal (Figure 1-a). Six days later he was given a test dose of 250 mg. procainamide by mouth. His temperature began to rise after six hours and reached a climax of 104.4° F. nine hours after application. Thirty hours after the test dose, the temperature returned to normal (Figure 1-b). The patient was discharged on April 30, 1968, and was seen May 13 in good condition and without any complaints.

Comments

If an otherwise unexplained fever occurs during administration of procainamide, it is essential to withdraw the drug and note whether the fever promptly remits. The patient described in this report had an acute febrile episode with no leukocytosis and negative studies for infection, leading to the suspicion that he might have a drug fever. Withdrawal of the drugs and subsidence of fever confirmed this suspicion. Recurrence of the fever after challenge of procainamide essentially established the diagnosis of fever due to procainamide (Figures 1-a and 1-b).

The origin of drug fever may be on an allergic basis, but the immunologic mechanism is still not clear. There are four different possibilities for the cause of fever in relation to drug administration: (1) nonspecific cause (impurities), (2) specific chemical effect, (3) Herxheimer's reaction, (4) allergic reaction with or without manifestations of cutaneous, vascular or gastrointestinal type. Fever secondary to the use of procainamide (Pronestyl®) is probably in the latter category.

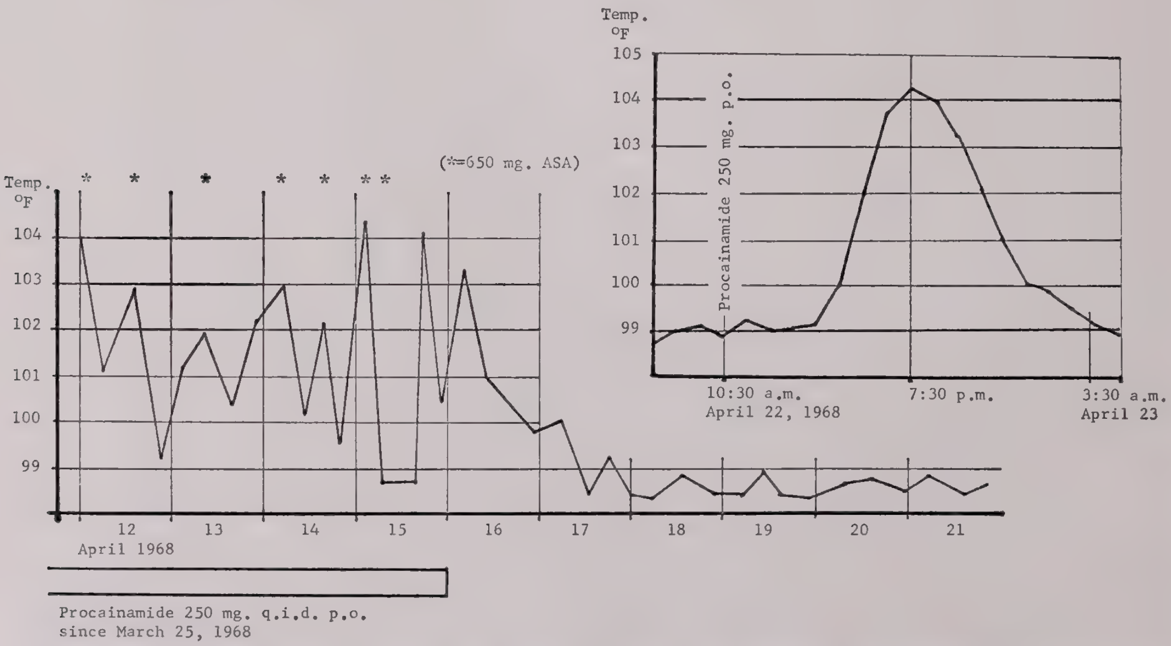

Fig. 1a—Temperature curve of patient with procainamide fever.

Fig. 1b—Provocation of procainamide fever by test dose.

This type of drug fever generally occurs one to two weeks after the onset of procainamide therapy in sensitive individuals. In our case and in the literature, no additional sensitivities to other drugs were noted. It is also interesting that several of the reported cases and our patient had tolerated procaine as a local anesthetic without adverse reaction. This allows the suspicion that the replacement of the ester linkage of procaine by an amide linkage not only leads to its more potent anti-arrhythmic effect but also enhances allergization.

A comparison of our patient with nine cases of procainamide fever previously described in the literature[1-7] is given in the Table. Other side effects to procainamide, such as skin rashes, agranulocytosis or connective-tissue diseases, including a lupus erythematosus-like syndrome,[8,9] were not observed in our patient. Although there are more cases reported with a lupus-like syndrome than with fever alone in connection with procainamide, the possibility cannot be excluded that in some of the latter cases fever might have been the first sign of a lupus-like syndrome. Adverse reactions to procainamide are obviously not very rare: Fakhro et al.[10] reported that fifteen out of fifty patients treated with procainamide showed one or more symptoms of the lupus-like syndrome.

The current, all too commonly practiced, polypharmacy, more often with rather new drugs, may be expected to lead to an increase of adverse reactions. Therefore it is most important to keep in mind the possibility of side effects of an administered drug to explain a patient's otherwise cryptogenic fever. In such cases, withdrawal of all drugs will promptly result in defervescence.

Comparison of references from the literature to our case of drug fever due to procainamide.

Summary

A 64-year-old male patient demonstrated drug fever due to procainamide. Fever started 16 days after commencement of Pronestyl® therapy, 250 mg. four times daily by mouth. The day after discontinuance the temperature dropped to normal, but later rose briefly again after a single provocative dose of 250 mg.

Housemaid's Knee

Awe of doctors and wonderment over their behavior is characteristic of the human race. We patients love to tell yarns tending to show that our doc is just a regular guy like anybody else, but we don't really believe it. And for good reasons.

Doctors know too much about us. Scrape an inch off one of them and you'll discover the world's darkest and dankest secrets piled in there. We have all told doctors things that we would not confess ordinarily even to ourselves alone in a room with the shades down and the door locked. We hold up our souls for their inspection. We also hold up every item of anatomy and, if the doctors can't find anything interesting on the outside, we let them poke around inside with flashlights.

Other circumstances set them beyond the pale. Though packed with medical knowledge, they dole it out as stingily as a man letting you smell the cork of his bottle of Napoleon brandy. For two years I have sought by cajolement, by trickery, by outbursts of temper, by sicking one doctor on another, to learn precisely what ails me. My impression to date is that I suffer from a mild form of housemaid's knee and I've abandoned hope of ever learning more.*

Opinion of the Public

People come in three classes: the few who make things happen, the many who watch things happen and the overwhelming majority who have no idea what happened.—News, Woonsocket, S. D.

Grand Rounds

Adult Scurvy*

RAFAEL CARMENA, M.D.
Minneapolis, Minnesota

THE FIRST RECORDED accounts of scurvy are to be found among the writings of the physicians who accompanied the Crusades in the XIII century. Vasco de Gama, who sailed round the cape of Good Hope in 1498, described how a hundred of his crew of 160 perished from scurvy at sea. Scurvy ran an extremely high incidence among the crews of most maritime expeditions during the 16th and 17th centuries, and it was also seen on land, particularly during wars and in prolonged sieges. The main manifestations were "putrid gums, lassitude, pain in the knees, and skin hemorrhages," and it was soon realized that they could be prevented and treated by eating fresh fruits and vegetables. Sir Richard Hawkins' "Observations in the Voyage to the South Sea," published in 1593,[1] contains an account of the prevention and treatment of the disease with lemon juice. Jacques Cartier (1535), during his exploration to Canada and what is now northern Minnesota, found that the native Indians prevented the disease by drinking a decoction of pine needles, which we now know contain ascorbic acid.

In 1734 Bachstrom[2] wrote that scurvy should be attributed solely to a total abstaining from fresh vegetables, foods and greens, and not to cold climates, sea air, eating salted meat, etc. A few years later James Lind (1753),[3] an English ship's surgeon, published his "Treatise on the Scurvy," wherein, by means of dietetic experiments with 12 scurvy patients, he demonstrated that oranges and lemons were the most effectual remedies. By 1804 regulations were introduced into the British Navy, making compulsory a daily ration of lemon or lime juice to all British sailors. This led to the almost complete eradication of scurvy in the British Navy, and to this day the nickname "limies" is applied to British sailors.

---

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, March 5, 1968.

Scurvy was a subject of interest for several scientific investigators of the 19th century. Hirsch (1860),[2] in his "Handbuch der historisch-geographischen Pathologie," concluded: "Scurvy appears when a special ingredient is lacking in nourishment and the disease disappears as soon as this substance is administered." This concept may well have instigated the theory of nutritional deficiencies. It was also around this time (1883) that Barlow published his classic observations on infantile scurvy.

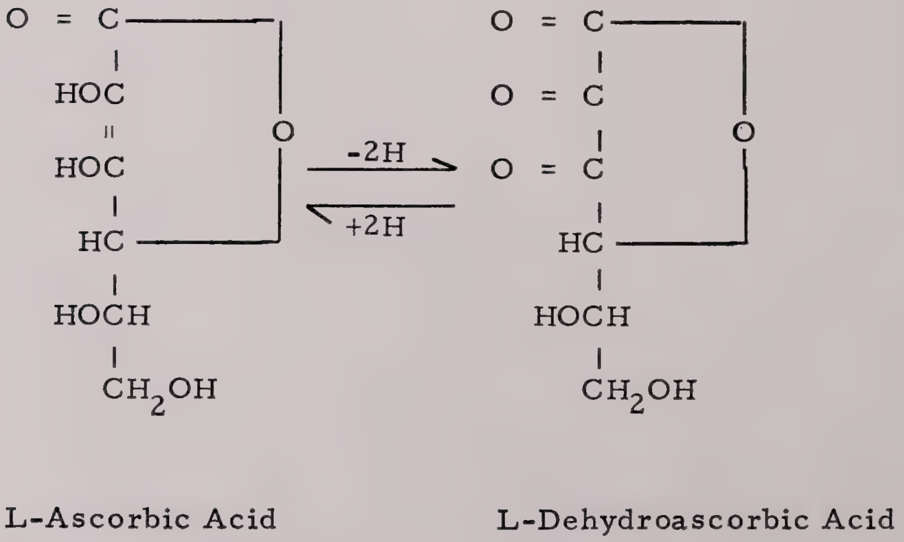
The era of experiments on nutrition began in 1881, when Lunin started animal experiments on the influence of diet on nutrition.[2] This lead to the discovery of polyneuritis gallinarum by Eykman in 1896, which founded the new theory of vitamins. In 1912, Holst and Frölich[4] fed guinea pigs exclusively on cereals and induced a disease essentially similar to scurvy, which could be cured by adding fresh vegetables and their extracts to the diet. The concept of vitamins was introduced by Casimir Funk in 1913. Diseases like scurvy, beri-beri and pellagra were called avitaminosis. The vitamin lacking in scurvy was called vitamin C.

In 1928 Szent-Gyorgyi[5] isolated from adrenal glands and cabbage leaves a crystalline substance which had an acid reaction and possessed strongly reducing properties. He called this substance hexuronic acid; but it was not until 1932 that hexuronic acid was identified with vitamin C and renamed ascorbic acid.

Chemistry

The structural formula of vitamin C was established in 1933 as a result of the work done by Haworth, Hirst and co-workers.[6]

Ascorbic acid forms colorless crystals which are freely soluble in water. It is a strong reducing agent and is therefore readily oxidized. The first oxidation product is dehydroascorbic acid, which can be reduced to ascorbic acid by hydrogen sulphide, cysteine and glutathione. Dehydroascorbic acid is as potent an antiscorbutic as ascorbic acid itself (Figure).



Figure

Biochemistry and Physiology

Species Specific

The only species for whom ascorbic acid is a vitamin are the primates, the guinea pig, an Indian bat and a bird (the red vented bulbul). These species depend exclusively on dietary sources for vitamin C since they lack the enzyme required to carry on the reaction from keto-gluconolactone to ascorbic acid.

Source

Good dietary sources of ascorbic acid are fresh fruits (strawberry, orange, lemon, grapefruit) and fresh vegetables (brussel sprouts, cauliflower, cabbage, tomato, potato). It is generally absent from dried, canned or preserved foods unless the process is carried out anaerobically. However, freezing or dehydration retains the vitamin. Vitamin C is lost during the cooking of vegetables by too much cooking water, over-cooking, etc. Foods devoid of vitamin C include meat, fish, eggs, fats and oils, and cereal products (Table 1).

Absorption

Ascorbic acid is absorbed from the small intestine by a simple diffusion mechanism, the rate of absorption varying directly within the concentration of ascorbic acid ingested. Under normal conditions intestinal absorption of ascorbic acid from the intestine is almost complete, because as shown by Farmer et al.[7] on normal intakes the fecal excretion is negligible. Under abnormal conditions (diarrhea, achlorhydria) intestinal absorption of ascorbic acid may be incomplete.

After absorption, ascorbic acid diffuses freely from blood to all body tissues. The major part of vitamin C lies inside the cells, not in the plasma or fluids. Normal human plasma contains about 0.5-1.5 mg. of ascorbic acid per

TABLE I
Ascorbic Acid Content of Some Fruits
Data from Bicknell and Prescott[1]

Fruit	Ascorbic Acid in mg. per 100 Gm. or 100 ml.
Apple	8
Grapefruit, juice	50
Lemon, pulp	15
Lemon, peel	150
Lemon, juice	70
Lime, juice	60
Orange, juice	80
Orange, Navel	90
Orange, Jaffa	40
Orange, Valencia	90
Tangerine, juice	50
Cabbage, raw	100
Cabbabe fresh, boiled 10′	45
Cabbage fresh, boiled 60′	15
Cabbage fresh, boiled 90′	5

100 ml.; RBCs contain about twice as much, and WBC and platelets contain 20 to 40 times more than plasma.[8] The adrenal cortex and the anterior pituitary contain more than any other organ or tissue in the body.

Metabolism

The vitamin exists in the body largely in the reduced form (ascorbic acid) in reversible equilibrium with a relatively small amount of dehydroascorbic acid (oxidized form). Ascorbic acid is partially destroyed and partially excreted by the body. It is believed that on a daily intake of 100 mg. about 50 percent undergoes metabolic conversion to CO_2 (excreted by the lungs) and oxalic acid (excreted in the urine). It is also excreted as ascorbic acid in the urine, the total amount being some 20 mg. in 24 hours.

There is no evidence that any particular organ or tissue serves as a storage reservoir for vitamin C. However, the body probably does have mobilizable reserves of ascorbic acid since clinical manifestations of scurvy develop in man only after several months of being on an ascorbic acid-free diet. It has been estimated[9] that the total vitamin C content of the human body when fully saturated ranges between 4 to 6 Gm., of which perhaps 200 mg. is present in the plasma and extracellular fluid, and the rest within the cells.

There is a renal threshold for vitamin C excretion. The vitamin is excreted by the kidneys in large amounts only when the plasma levels exceed this threshold, which is approximately 1.4 mg.%. Therefore, when the body is saturated with ascorbic acid, the plasma level will be approximately that of the renal threshold; when further amounts of vitamin C are administered most of it escapes into the urine. When the tissues are not saturated and plasma level is low, the ingestion of ascorbic acid results in little or no renal excretion. This is the basis for the so-called "saturation test."

Function

The precise functions of ascorbic acid in tissue metabolism are totally unknown; so also are the biochemical lesions which cause scurvy. Vitamin C stimulated more inquiry than perhaps any other vitamin, but we have not yet gotten an answer as to what it does in the body. Following is a short list of the metabolic functions vitamin C is probably related to.

Tissue Oxidation and Reduction

Shortly after its discovery it was thought that the main role of ascorbic acid was to act as hydrogen acceptor in tissue oxidation mechanisms. However, we lack any good evidence of this, and most investigators now agree that ascorbic acid acts probably as an anti-oxidant by providing a supply of readily available hydrogen. This goes along with the fact that vitamin C is present largely in the body in the reduced state (ascorbic acid) and only a small part in the oxidized form (dehydroascorbic acid). Thus, ascorbic acid may play an important role in keeping SH-activated enzyme systems in their reduced state.

Tryosine Metabolism

It is well known that scurvy patients metabolize tyrosine incompletely when given extra amounts of this amino acid.[10,11] This led to the discovery that ascorbic acid protects the enzyme p-hydroxyphenylpyruvic acid oxidase from inhibition by its substrate, but does not act as a cofactor for that enzymatic step. Moreover, other reducing agents have been shown to be equally effective in "protecting" the same enzyme.

Bone and Connective Tissue Metabolism

The synthesis of collagen requires ascorbic acid.[12] It has also been shown that scorbutic guinea pigs not only fail to synthesize new collagen fibers but show a rapid collagen degradation. Although the synthesis of collagen is a very complex matter and not totally understood as yet, present evidence suggests that ascorbic acid may intervene in the conversion of proline to hydroxyproline, before the synthesis of the peptide chain. Hydroxyproline is not synthesized in the absence of ascorbic acid, and it is important to remember that exogenous hydroxyproline is not incorporated into collagen.

Ascorbic acid is also essential for the formation of bone and cartilage; the proper functioning of osteoblasts and odontoblasts depends on it. In scurvy, bone formation ceases; hence the typical low serum alkaline phosphatase values. The osteoblasts are unable to synthesize osteoid and become surrounded by liquid with a region of edematous connective tissue appearing at the end of the diaphysis. In growing bones, subperiosteal hemorrhages frequently occur. Fractures heal slowly, as do wounds.

Adrenal Glands

No other organ in the body contains as much ascorbic acid as the adrenal cortex (about 5 mg. of ascorbic acid per gram of dried tissue). However, we simply do not know what ascorbic acid does in the adrenal. There is no evidence that it is involved in the synthesis of cortical hormones. Patients with scurvy have normal adrenal function, and patients with Addison's disease do not develop scurvy.[10]

*Erythropoiesis**

Anemia (of no particular type) is frequently seen in cases of scurvy and is usually corrected by the administration of ascorbic acid alone. Although this is still a controversial problem, most investigators now agree: (a) *Ascorbic acid plays some role in the metabolism of folic acid;* it seems to be essential for the conversion of folic acid into its active form, folinic acid (citrovorum factor). This has recently been questioned by Cox et al.[13] who found no evidence for that theory but concluded that ascorbic acid is indeed involved in the protection of folic acid reductase, maintaining a higher concentration of folic acid coenzymes. (b) *The transfer of plasma-bound iron into the liver and its incorporation into ferritin in this tissue requires the presence of ascorbic acid.* Since ascorbic acid is rather specific for this reaction and cannot be replaced by other reducing agents this could well represent a unique biochemical function for vitamin C.[14]

Cardiovascular System

It has been shown[15] that the peripheral vascular system requires vitamin C to maintain its responsiveness to stimulation with epinephrine. Ascorbic acid is involved in the maintenance of good capillary tone and resistance. It is also known[16] that patients with scurvy may develop electrocardiogram abnormalities (prolonged PR, elevation of ST) that are corrected by the administration of ascorbic acid. This leads to a topic that has received particular attention from Russian investigators: the effects of vitamin C on serum lipids. According to Miasnikova and Tiapina[17] high doses of vitamin C (500 mg. I.V. daily) would reduce serum cholesterol and improve the clinical status of patients with myocardial ischemia. However, the recent work of Samuel and Salchi[18] has failed to confirm this.

---

*See Test Your Word Score Page 759.

Other Possible Functions

Ascorbic acid has been implicated in many different body processes: carbohydrate metabolism, formation of antibodies, activity of serum complement, phagocytosis, detoxicating function, etc. However, we lack good experimental evidence to support any such theory.

Clinical Manifestations of Scurvy

Under Experimental Conditions

There are three stages in the development of experimental scurvy in humans:[9,19] (1) initial stage, with changes in the vitamin content of the blood and no clinical signs; (2) clinical scurvy, with changes in the skin, gums and impaired wound healing; (3) final stage with hypotension and danger of death. Our present knowledge is based mainly on the work of Crandon[9] who induced scurvy in himself and on the Medical Research Council experiment[19] in 1948.

Symptoms of scurvy appeared after about 150 days on a vitamin C-free diet. They consisted of keratosis of the hair follicles in the skin and perifollicular hemorrhages. After six months, swelling and hemorrhages of the gums appeared, and wound-healing processes were affected. Later on, signs of cardiac ischemia and peripheral collapse may appear, together with loss of neuromuscular coordination and marked asthenia, forcing the end of the experiment. No anemia, bleeding, weight loss or susceptibility to infection were noted.

Naturally Occurring in Adults

Most cases are encountered among old men living alone ("bachelor scurvy") whose diet is grossly imbalanced and devoid of sources of ascorbic acid. Ignorance, apathy, alcoholism and poverty are the usual basis for its development. In some cases scurvy is only one of the many manifestations of malnutrition. A fair number of cases have been reported among people with gastrointestinal disturbances (peptic ulcer, diverticulosis, chronic cholecystitis) who were advised to avoid fruits and vegetables and followed the advice too drastically. It is worth noting that the Sippy diet affords a daily intake of vitamin C of only 0.5 mg.,[20] obviously not enough to cover the daily requirements.

Adult scurvy tends to appear more commonly in the spring, reflecting the relative lack of fresh fruits and vegetables during the winter months. The most frequent clinical manifestations are:

1. Malaise, weakness, lassitude
2. Perifollicular hemorrhages (abdomen, thighs and forearms)
3. Petechiae and ecchymoses
4. Swollen and bleeding gums with loss of teeth
5. Anemia, leukopenia
6. Mental confusion
7. Postural hypotension and syncope
8. In fatal cases, vomiting and "addisonian crisis" precede death.

Cutforth[21] has reported 11 cases of adult scurvy seen in a teaching hospital in London over a six-year period. There were ten men and one female; the average age was 65 years; and all but one were living alone, on diets of tea, toast, bread and butter, meat and fish-paste sandwiches. Three of the patients had a previous history of duodenal ulcer and were purposely avoiding fruits and vegetables. All of them had been eating the above diet for a period longer than six months prior to admission. The characteristic manifestations are recorded in Table 2.

TABLE 2

Symptoms Found in 11 Patients with Scurvy[21]

Symptom		Number of Patients
Bruising		11
Extensive spontaneous extravasation present in six of them		
Anemia		9
Normocytic normch.	5	
Macrocytic	4	
Pain in limbs		8
Anorexia		8
Lethargy		6
Purpura		6
Hyperkeratotic hair follicles		6
Swollen gums		2

(Seven of the cases were edentulous)

Ascorbic acid in doses of 600 mg. daily was given to all the patients. Five received a standard ward diet, ascorbic acid and no other medication; the remaining six were given ferrous sulphate and vitamin B complex as well as ascorbic acid. All cases responded immediately to therapy; the purpura and smaller bruises were gone within one week and the hemoglobin levels became normal within a month. There was no difference in the response of the two groups.

Chazan and Mistilis[22] reported seven cases of adult scurvy seen at Boston City Hospital during a one-year period. The average age was 65 years; six were single men living alone. All gave a history of poor dietary intake; none could recall having eaten fresh fruits or vegetables for at least six months prior to admission.

Symptoms

Ecchymosis

Tables 3 to 5 show the most important symptoms, physical findings and biochemical data. It is worth noting that a huge ecchymotic area on a lower limb was the outstanding complaint in three instances. Five of the patients had a relatively low blood pressure. In fact, two of the patients had sudden, profound hypotension with no response to therapy and died. Post-mortem examination failed to reveal an immediate cause of death.

Low Blood Pressure

The work by Crandon[9] in 1940 showed that low blood pressure in human experimental scurvy was not due to blood loss or reduction in blood volume. It was easily corrected by administration of ascorbic acid. The only explanation we have so far for the hypotension encountered in human scurvy is that the peripheral vascular system becomes less responsive to epinephrine and more prone to vascular collapse and shock. There are experiments in scorbutic animals[1] suggesting that relative adrenal insufficiency may be responsible for the hypotension; but this observation has not been substantiated in man.

Anemia

The incidence of anemia in scurvy has been the subject of numerous papers ever since Mettier, Minot and Townsend[23] gave the first detailed account in 1930. According to recent reviews, anemia is quite common in adult scurvy. Goldberg,[24] reviewing 55 cases of scurvy seen at the Western Infirmary in Glasgow over a 23-year period, found that 49 (89%) of them had hemoglobin values below 12 Gm. on admission. Cutforth[21] found anemia in nine out of eleven patients with scurvy; Shafar[25] has reported severe anemia in two of the three cases seen over eight months at a public hospital. Chazan and Mistilis[22] found anemia in all seven patients reported, the condition being severe (hematocrit values below 23%) in four of them. Recently Cox et al.[13] and Asquith[27] have reported several cases of anemia in patients with scurvy.

There are three factors to which the anemia of scurvy has been attributed: (1) loss of blood (from the gut or into the tissues); (2) lack of blood forma-

TABLE 3

Summary of the Presenting Symptoms. Data from Chazan and Mistilis[22]

Case No.	Weakness and Lassitude	Weight Loss	Anorexia	"Red Spots" on Arms and Legs	Swelling and Ecchymosis of Extremities	Syncope Dizzy Spells	Painful Gums

VII	88	115/70	+	+	+	Edentia	+	+	0

tion; and (3) increased blood destruction. It is quite clear now, however, that the first factor is of little importance. Cutforth[21] found no correlation between the severity of the anemia and the degree of extravasation of blood into the tissues. Goldberg and Cox[24] have reported consistently negative tests for occult blood in feces in all their patients with scurvy, and the same was reported by Chazan and Mistilis. The last two factors (lack of blood formation and increased blood destruction) have been supported by clinical and experimental observations. As was mentioned, ascorbic acid is related to folic acid metabolism and to the intestinal absorption of iron and the transfer of iron to the ferritin form. It has been shown that blood transfused into scorbutic patients survived poorly. By using 51-Cr, Goldberg[24] demonstrated increased hemolysis in four of six scorbutic patients with anemia. The hemolytic process was corrected by the administration of ascorbic acid.

In summary, the anemia of scurvy is multifactoral in origin; and in the adult it conforms to no particular type: it may be normocytic or macrocytic, normochromic or hypochromic. In the majority of cases that we have reviewed, the anemia was of the macrocytic normochromic type and there was a high reticulocyte count initially. WBC and platelets are usually normal. The bone marrow is generally hypercellular. The serum Fe and IBC are normal or low.

In most cases the anemia is corrected by the administration of ascorbic acid alone. Folic acid sometimes provides benefit, the same as iron. It is evident that chronic general malnutrition, chronic liver disease, chronic infection and external blood losses complicate the type of anemia seen in scurvy and also complicate the therapy. In conclusion: ascorbic acid deficiency has a deleterious effect on blood formation. Whether this is a direct or an indirect effect through interference with folic acid metabolism has not been determined.

Mental Changes

Finally, striking mental changes have been reported in scurvy: confusion, depression and lethargy. They were noted by Cutforth[21] in more than half of his patients. As a rule, all mental changes clear up rapidly with the administration of ascorbic acid.

Diagnosis

The clinical diagnosis of scurvy is based upon the combination of poor dietary history, presence of hyperkeratosis of the hair follicles, perifollicular hemorrhages, ecchymosis and typical gum changes. The differential diagnosis should include the *purpuras* (low platelet count, prolonged bleeding time and clot retraction, drugs, fever and blood cultures for subacute bacterial endocarditis, lupus erythematosus preparations, etc.) ; *dilantin toxicity* may have similar gum lesions but gingivitis due to ascorbic acid deficiency seldom occurs without other florid manifestations of scurvy; *rheumatoid arthritis* also gives swollen joints but not bloody joint effusions; moreover the scorbutic patient will not have deformities such as are common to rheumatoid arthritis.

The following is an outline of laboratory diagnostic aids that should be used to confirm the clinical diagnosis:

Ascorbic Acid Levels in Blood and Urine

The plasma level of ascorbic acid falls too rapidly after the vitamin is removed from the diet and is of no diagnostic value. According to Crandon,[9] ascorbic acid levels in plasma fell to zero after 41 days of ascorbic acid deprivation, and signs of scurvy did not appear until day 134. Therefore, the plasma ascorbic acid level indicates the state of ascorbic acid nutrition for the preceding few weeks. A plasma level of 0 mg.% is compatible with but not diagnostic of scurvy. If ascorbic acid has not been administered previously, any amount of ascorbic acid found in plasma is incompatible with the diagnosis of scurvy.

The ascorbic acid level in the white cell-platelet layer (buffy coat) has diagnostic significance. Normal values are 25-40 mg. per 100 Gm. The buffy-coat level reaches zero after 125 days of ascorbic acid deprivation, paralleling the onset of scorbutic lesions. As Vilter[26] has stated, a value of 0 mg.% in the buffy-coat is the only laboratory evidence of scurvy.

Ascorbic acid almost disappears from the urine even before the level in the plasma is zero. Therefore, a low level of ascorbic acid in urine has the same significance as a low plasma level: it will make a diagnosis compatible but no more. This applies to a single collection as well as a 24-hour collection.

Saturation Test

This test depends upon changes in the urine and plasma ascorbic acid levels after an appropriate test dose. The usual technique is: (1) Administration of 100 mg. of ascorbic acid by intravenous injection; and (2) Determination of urinary excretion of ascorbic acid during the next three hours. A normal, well saturated person will excrete 50% of the test dose; a depleted person will excrete 15% or less, and a scorbutic person will excrete less than 5% of the test dose.[26] The test indicates only that a person's tissues are saturated or unsaturated. The results can be compatible but never diagnostic of scurvy. This is due to the fact that the kidneys will reabsorb most of the vitamin when the tissues are at all unsaturated.

Other Tests

Test for capillary fragility, x-ray of the bones, increased tyrosil derivatives, etc., have been used but are not diagnostic. It is of importance to mention that in infantile scurvy x-rays are the most helpful tool for the diagnosis.

Treatment and Prevention of Scurvy

Ascorbic acid is the specific therapy for scurvy. The vitamin is usually administered by the oral route but it may also be given by intramuscular or intravenous injection. The tablets are available in 25, 50 or 100 mg. of the vitamin; the solution usually comes in 100 mg. per 5 ml. In the majority of cases of scurvy, 100 mg. of ascorbic acid daily and a well balanced diet are enough to produce rapid cure. The dose should be increased in the presence of tuberculosis, pregnancy, lactation, malignancies or hyperthyroidism, conditions where the daily requirements for vitamin C are increased. One gram of ascorbic acid may be administered daily until the symptoms are under control. There is no evidence of toxic effects from large doses of vitamin C.

The estimated daily requirements of vitamin C vary according to different sources. The National Research Council of the U. S. recommends a daily allowance of 70 mg. The British Medical Association has stated that a daily intake of 30 mg. of vitamin C would provide a good margin of safety. Their statement is supported by the experiment conducted in 1948 with 20 volunteers where seven of them were kept fit on a daily intake of only 10 mg. of ascorbic acid; moreover, six individuals in whom scurvy was induced in this experiment were relieved of the disease by the same daily dose. The question remains though as to whether this daily intake which obviously prevents scurvy is enough. It is, in any case, insufficient to maintain the body in a state of full saturation. In animals which are capable of synthesizing vitamin C the vitamin content in the different organs has a constant value, i.e., they are saturated.[2] It would appear then that the state of saturation is the most favorable for man as well.

The Campbells Are Coming*

The lilting melody of the song, "The Campbells Are Coming," is that of an old Irish folk song—subsequently appropriated by the Scotch to narrate the rousing exploits of their hero, John Campbell.

"The Campbells are comin', o-ho o-ho,
The Campbells are comin' to bonnie Lochleven."

The verses go on and on.

Who were the Campbells? Whence were they comin' and when and why?

The Campbells were stout-hearted loyalists (English and Scottish) who, under John Campbell in 1715, assembled in the Highlands to engage and rout the Jacobites (rebelling Scots) at Sheriffmuir in the Midlothian region of southern Scotland.

John, titled 2nd Duke of Argyll, was one of the illustrious Campbells, a long and historic line of Scottish earls and dukes: patriots, statesmen, soldiers, administrators. Not only do the annals of history assure John's name and fame; fiction too has immortalized him as one of the heroic characters in Sir Walter Scott's "Heart of Midlothian."

The melody is that of an old Irish folk song, "An Seanduine" (meaning "old man"). There had been several variations of this song until its first publication about 1745. Other printings followed in 1747, 1756, and 1761. Somewhere in this period the Scotch appropriated the melody, and it became "The Campbells Are Coming" with certain variants. The standardized version was produced by the Scottish musician Finlay Dun in the early part of the nineteenth century.

*See editorial page 751.

For elderly patients
in need of a mild tranquilizer
consider **Tybatran**®
brand of tybamate

(When you consult
the Prescribing Information
you may agree
it makes good sense)

PRESCRIBING INFORMATION

Indications: Tybatran (tybamate) has afforded symptomatic improvement in a variety of psychoneurotic disorders, especially in the treatment of the anxiety and tension components of psychoneuroses. Anxiety states manifested somatically have responded to Tybatran (tybamate).

Tybatran (tybamate) has been useful in the control of agitation in the aged and in the alleviation of some of the adverse emotional accompaniments of senility.

Tybatran (tybamate) has been used with benefit in the treatment of depressive symptoms associated with anxiety and other symptoms of psychoneuroses. However, it is not indicated for primary treatment of depressive states. It is not an antipsychotic agent, although it has been used as adjunctive therapy in some psychotic patients.

Dosage: One 350 mg. capsule, 3 times daily and two at bedtime is suggested as the adult starting dose. Adjust to suit individual requirements. Daily doses above 3000 mg. are not recommended.

Contraindications: Known hypersensitivity to tybamate. Since no studies have been done with this drug in human pregnancy, it should not be used in pregnancy unless the potential benefit outweighs the risk.

Warnings: Administer cautiously to patients receiving phenothiazines or other CNS depressants or having history of convulsive seizures (See Adverse Reactions). Consider possibility of additive actions with alcohol or other psychotropic agents, particularly phenothiazines or MAO inhibitors.

Precautions: Avoid abrupt withdrawal after prolonged use, although withdrawal symptoms have not been reported to date. Exercise caution in addiction-prone individuals. If symptoms of hypersensitivity occur, discontinue at once and initiate appropriate symptomatic treatment. Avoid activities requiring optimal mental alertness if drowsiness or vertigo are present. As with any new drug, use cautiously in patients with history of drug allergies, blood dyscrasias, and hepatic or renal disease; periodic measurements of hepatic, hematopoietic and renal function should accompany prolonged and/or high doses.

Adverse Reactions: Most frequent reactions, rarely requiring discontinuation of tybamate, include drowsiness, dizziness, nausea, insomnia, and euphoria. There have been a few reports of skin rash, urticaria, and pruritus. Rare side effects include hyperactivity, fidgetiness, flushing, and tachycardia, suggesting excessive stimulation; also ataxia, unsteadiness, confusion, feeling of unreality, "panic reaction," fatigue, headache, paresthesias, vertigo, gastrointestinal disturbances, glossitis, and dry mouth. Grand mal or petit mal seizures have been reported in a few hospitalized psychotic patients receiving tybamate (up to 6000 mg. daily) together with phenothiazines and other psychotropic agents, but not with tybamate alone. Consider the possibility of rare, serious adverse reactions such as may occur with the related drug, meprobamate. If excessive amounts are ingested, gastric lavage and symptomatic therapy, including central stimulants as necessary, are recommended. Before prescribing, consult package circular.

Supply: Tybatran (tybamate) is available in green, sealed capsules of three strengths: 350 mg., 250 mg., and 125 mg. Each strength is supplied in bottles of 100 and 500.

in cerebrovascular disorders

Arlidin increases blood flow

Arlidin decreases cerebral vascular resistance, increases cardiac output, helps maintain mean arterial pressure.

Arlidin helps control vasoconstriction, vasospasm, and ischemia.

Arlidin may thus relieve symptoms of cerebrovascular insufficiency, such as vertigo, lightheadedness, and mental confusion.

Arlidin also increases blood flow to the eye and inner ear to help manage ischemic disorders of those organs.

Arlidin is well tolerated and relatively free of severe adverse reactions.

DOSAGE: Usual effective dosage ½ to 1 tablet t.i.d. or q.i.d.; increased, if necessary, to 2 tablets t.i.d. or q.i.d. Parenterally, 0.5 cc. by subcutaneous or intramuscular injection; increased gradually to 1 cc. one or more times daily, as needed. SIDE EFFECT: Occasional palpitation. PRECAUTIONS: Use with caution in the presence of a recent myocardial lesion, paroxysmal tachycardia, severe angina pectoris, thyrotoxicosis. CONTRAINDICATION: Acute myocardial infarction.
SUPPLIED: Tablets, 6 mg., scored; bottles of 100 and 1000. Parenteral, 5 mg. per cc., 1 cc. ampuls (5 per box); 10 cc. multiple-dose vials (1 per box). CONSULT PRODUCT BROCHURE.

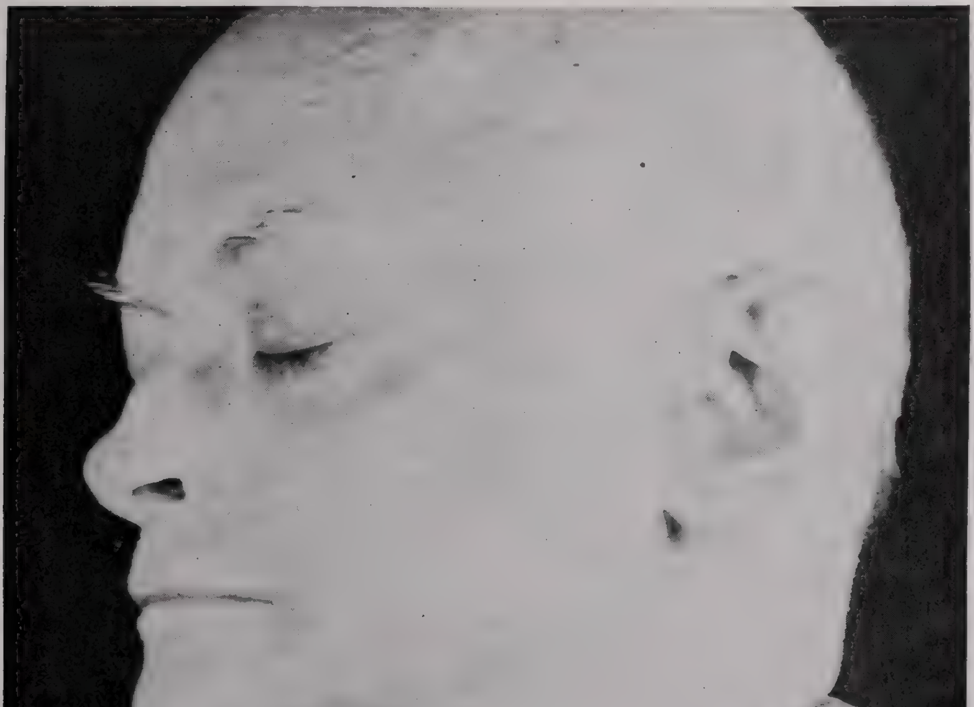
Dermatology

Radiodermatitis

RADIODERMATITIS is an acute or chronic inflammatory disorder caused by the application of x-rays or radium. Cases are now rare. Care and precaution should govern the use of ionizing radiation on the skin. Its use in the treatment of benign dermatoses has decreased greatly within the past decade because of the development of antibiotics, steroids, etc. There has also been a tendency to use lower kilovoltage (60 kv). Approximately 300 to 400r administered to one square inch of skin will produce an erythema in seven to 10 days; larger doses invoke more intense reactions (acute radiodermatitis). Fractional treatment infers the application of small amounts (50 to 75r) at weekly intervals. In massive or intensive treatment the total dose is applied only once (e.g., 1500r sharply localized to a plantar wart). Divided dosage means that the total amount is split into several smaller fractions given daily, every other day, twice weekly, etc. For example, if a cutaneous carcinoma were to be treated with a total dose of 3000r, the individual doses might be divided into 6 of 500r each.



Figure—Chronic radiodermatitis. Patient had psoriasis and was treated excessively with fractional doses of x-rays.

Acute Type

First degree radiodermatitis consists of erythema with slight burning, itching, and scaling, which disappears after a few days or weeks. There may be temporary alopecia; pigmentation develops later.

Edema, intense erythema, and vesiculation typify second degree radiodermatitis, followed by exudation, erosion, and crusting. There is loss of hair which may be permanent. Sebaceous and sweat glands become less active. Atrophy and telangiectasia appear several months later.

Necrosis and ulceration characterize third degree radiodermatitis. Recovery may take several months; in some instances the ulcerations are so indolent that they never heal.

Chronic Type

This form may develop after the acute type or insidiously as a result of many fractional (suberythema) doses. The skin is dry, thin, smooth, shiny, and sensitive to trauma. Itching and burning are prominent symptoms. There is both hyper- and hypopigmentation and telangiectasia. The nails may be striated, discolored, brittle, or lost. As the disorder progresses multiple keratoses appear. Carcinoma develops in about 20% of the cases, usually squamous rather than basal cell in type. Sarcoma may arise in areas of radiodermatitis.

Mild radiodermatitis responds to measures used for corresponding phases of dermatitis due to other causes. Ointments or creams containing a steroid and an antibiotic are helpful in first degree radiodermatitis. If vesiculation is present, moist compresses of Burow's solution are effective. Severe cases, with necrosis and ulceration, require excision followed by grafting.

From an 18th Century French Drug Dictionary

Ickey!

"All parts of man, his excrescences and excrements, contain oil and sal volatile, combined with phlegm and earth. Skull, brain, and calculus are employed in medicine, and are referred to in their proper places. Burning hair, smelt by patients, will counteract the vapors. Moss of the human skull, human blood, and human urine all have their uses in medicine. The saliva of a robust young man, taken fasting, is an antidote against the bites of serpents and mad dogs. Wax from the ears is good against whitlows. Nails from the fingers and toes, given internally either in substance or infused in wine, make a good emetic. Women's milk is pectoral, good in phthisis, and useful to apply to inflamed eyes. Fresh urine, two or three glasses drunk in the morning fasting, is good against gout, hysterical vapors, and obstructions. It may also be applied externally in gout and in skin complaints. Excrement of man can be applied to anthrax, plague bubos, and quinsies. Dried and powdered, it is recommended in epilepsy and intermittent fevers. Dose, one scruple to a drachm."*

Overweight

After a month on a new diet, Mrs. Jones was asked what she weighed. "One hundred and plenty," she replied.

Laboratory Letter

Three Lipid Tests

THREE LIPID TESTS—cholesterol, triglyceride, and lipoprotein electrophoresis—are now available in many laboratories. In this letter, I wish to speak to you about how you can use these tests to pin down what type of hyperlipoproteinemia your patient has.

Briefly, the facts on fats are these. At least five lipid disorders exist. Each has either a high cholesterol, a high triglyceride or elevations of both. And each carries its own symptoms, has its own outlook, and responds differently to diets or drugs. All, and here is this letter's gist, can usually be defined by three tests—cholesterol, triglyceride, and lipoprotein electrophoresis—and your knowledge of the patient's past and present state.

But how, you may ask, should I investigate patients in whom I suspect a lipid disorder? I would suggest you first order a cholesterol and triglyceride, especially if you spot a milky or turbid plasma from a fasting patient after it has been stored overnight at 4°C. If both tests are normal, your patient probably does not have a hyperlipoproteinemia. If either test is up, however, lipoprotein electrophoresis may help you define a specific type of hyperlipoproteinemia, as indicated by the list below.

					Food Sensitivity		
Type	Serum	Chol.	Trigly.	Lipid Electrophoresis	Fat	Carbohydrates	Clinical* Information
I	creamy	normal or high	high	chylomicron band; other lipoproteins down	yes	no	Rarest type; familial; occurs in children and causes bouts of abdominal pain and xanthomas; to treat, limit fats to 20% of calories.
II	clear	high	normal or high	beta-lipoprotein up	no	no	Most common type; patients may have xanthomas in tendons and xanthelasma and family history of coronaries before 50; tend to have premature infarcts; may be secondary to mxyedema, myeloma, macroglobulinemia, nephrosis, and liver disease; low cholesterol diets and lipid lowering drugs may help if condition detected early.

---

*All patients except Type I will respond to some degree to diets low in cholesterol and high in unsaturated fats. Types with high triglycerides, III, IV, and V, may all present with mild diabetes, mild obesity, and early coronary artery disease. If these patients reduce, take in less than 50 grams of carbohydrate each day, and eliminate pure sucrose from their diet, their triglyceride levels (and usually their cholesterol values) will fall. For details on diets, consult: Levi, R. I., and Fredrickson, D. S.: Diagnosis and Management of Hyperlipoproteinemias, Amer J Cardiology, 22:576-586, 1968; and Wessler, S., and Avioli, L. A.: Classification and Management of Familial Hyperlipoproteinemia, JAMA, 207:929-933, 1969.

Type	Serum	Chol.	Trigly.	Lipid Electrophoresis	Food Sensitivity		Clinical Information
					Fat	Carbohydrates	
III	clear, cloudy, or milky	high	high	pre-beta and beta-lipoproteins up "broad beta disease"	no	yes	Uncommon; patients may have xanthomas in palms, arcus senilis, but often coronary disease first sign. Therapy consists of weight control and low fat, low cholesterol, isocaloric diet. Atromid-S and cholestyramine effective.
IV	clear, cloudy, or milky	high or normal	high	pre-beta lipoprotein up	no	yes	Fairly common in overweight patients with mild diabetes; men with this type may have infarcts before forty. Responds to weight reduction. Use sugar-restrictive low carbohydrate, low-calorie diet. Alcohol consumption also ought to be reduced.
V	turbid or milky	high	high	chylomicron band; pre-beta lipo-proteins up	yes	yes	May present as abdominal pain in late teens or may be secondary to insulin-dependent diabetes, pancreatitis, alcoholism or nephrosis, glycogen storage disease, myxedema and acute metabolic processes. Treat high-protein, low-calorie diet.

It's the Law

Leaving Sponge in Body Not Necessarily Negligent

A physician removed a cancerous tumor from a patient's lung. A routine x-ray, taken the following day, disclosed a surgical sponge in the chest cavity. The operative procedure had been difficult, associated with the loss of eight units of blood. Nearly 100 sponges were used during the progress of the operative procedure. The usual safeguards concerning retained sponges were observed. In this case, the sponge count at the completion of the procedure was reported as correct. In addition, the operative note indicated that the chest cavity had been explored by the operating surgeon for evidence of retained sponges and none were found.

Several days later, the patient was returned to the operating room for removal of a sponge along with some clotted blood and old fibrin.

The jury found that the physician was not negligent under Minnesota law. The mere fact that the sponge was left within the thoracic cavity is not evidence of negligence. The patient was not awarded damages.

"No."—Miller v. Tongen, 161 N.W. 2d 686 (Minn., Sept. 27, 1968). The Citation, Vol. 18, No. 5 December 15, 1968.

Review

Factors Influencing Vitamin B_{12} Absorption

FACTORS OTHER THAN those in classical Addisonian pernicious anemia are known to influence absorption of vitamin B_{12}. This report is a review of some of the factors implicated in faulty absorption of that vitamin. The case report presents an example of impaired vitamin B_{12} absorption in a patient who did not have classical Addisonian pernicious anemia.

Case Report

History

A 59-year-old white, widowed male was admitted to Hennepin County General Hospital on August 14, 1968, for impending delirium tremens. A previous admission in November 1967 was for an alcoholic seizure disorder following a long history of heavy alcohol ingestion. He was diagnosed as having parenchymal cerebellar degeneration, probably secondary to alcohol.

Physical Examination: On the present admission the blood pressure was 120/70, pulse 100, respiratory rate 12, and temperature 98 degrees. The patient was thin, uncooperative, unkempt, but in no acute distress, and was fairly well oriented. Pertinent physical findings included arcus senilis, poor skin turgor, sinus tachycardia and an enlarged liver palpable two finger-breadths below the costal margin.

Laboratory Findings

The admission hemoglobin was 13.2 gm/100 ml; the white count was 8,700 with a normal differential. After hydration the hemoglobin was 10 gm percent, the hematocrit 30 percent, the platelet count 127,000/ml, and the reticulocyte count 0.6%. Cell indices revealed MCV 105, MCHC 31.3, and MCD 8.1. Bone marrow on August 29, 1968, showed erythroid hyperplasia with toxic neutrophil changes and decreased bone marrow iron stores; peripheral morphology revealed a normochromic, macrocytic anemia. The serum iron was 40 mcg%, IBC was 150 mcg% with 27% saturation. A Schilling test without intrinsic factor on September 6, 1968, showed 4.0% urinary excretion. The serum folate level was 2.2 $m\mu$/g/ml and the B_{12} level was 1,300 $\mu\mu$gm/ml.

Hospital Course

The patient was placed on folic acid 15 mg daily by mouth and ferrous sulfate 300 mg tid by mouth. A reticulocytosis of 4-5% occurred with hemoglobin remaining at 10 to 11 grams with reticulocyte counts of 3 to 4%. A second folate level three weeks after the first determination was 25.8 mgm/ml. A Schilling test done at this time (without intrinsic factor) showed a urinary excretion of 20.3%.

The reticulocytosis has continued and his hemoglobin has risen to 12.6 gm percent.

The results of the Schilling tests done on this patient suggest that the low initial vitamin B_{12} absorption was probably related to folate and/or iron deficiency, since the Schilling tests became normal after administration of folic acid and iron.

Classical Addisonian Pernicious Anemia

The clinical features of pernicious anemia were fully described by Addison in 1855; and the signs and symptoms of sore tongue, numbness, tingling and weakness, together with macrocytic anemia and achlorhydria form a well known clinical picture.[1] The response of this disease to parenteral vitamin B_{12} therapy implies a defect of absorption of this vitamin somewhere along the alimentary tract.

The gastrointestinal absorption of physiologic quantities of vitamin B_{12} may be divided into three phases:

1. Secretion by the gastric mucosa of a factor of unknown chemical structure designated intrinsic factor, to bind vitamin B_{12}.
2. Attachment of the intrinsic factor-vitamin B_{12} complex to the intestinal mucosa of the ileum by a calcium-dependent bond. The role of calcium is emphasized by lowered serum B_{12} levels and impaired absorption in man after the use of oral calcium-chelating agents.
3. The release of vitamin B_{12} at or within the intestinal mucosa by a substance with activity assumed to be enzymatic.[2]

Congenital Abnormalities of B_{12} Absorption and Utilization

Juvenile Congenital

Juvenile "congenital" pernicious anemia is characterized by vitamin B_{12} deficiency appearing in early life secondary to a congenital lack of intrinsic factor but with no other abnormalities of the stomach or its secretions.[3] This type responds to oral intrinsic factor supplementation, differentiating it from other causes of B_{12} deficiency in children. The diagnosis can be made by the following criteria: absence of gastric intrinsic factor activity; normal gastric mucosa histology; free hydrochloric acid in gastric juice; abnormal Schilling test; absence of serum antibody to intrinsic factor and parietal cells; correction of B_{12} absorption defect with intrinsic factor; no associated polyendochrinopathies (see below). The genetic basis for this disease has not been delineated.[3]

Familial Malabsorption

There are other types of pernicious anemia in children. Familial selective malabsorption of vitamin B_{12} is a rare, genetically determined disorder characterized by an isolated defect of vitamin B_{12} absorption and persistent proteinuria. Patients with this disorder also have free gastric acid, secrete adequate amounts of intrinsic factor and have a normal gastric mucosa. The mechanism responsible for failure to absorb B_{12} in the presence of intrinsic factor is obscure, although an intestinal defect has been postulated. Antibody activity against intrinsic factor remains a possible but unproven mechanism. Parenteral vitamin B_{12} therapy controls the disease. Approximately twenty-seven cases of this disorder have been documented.[4,5,6]

Endocrinopathies

There may be an association of pernicious anemia in children with endocrinopathies such as familial and idiopathic hypoparathyroidism and familial Addison's disease. It has been suggested that this condition is mucoviscidosis.[7,8]

Transitory intestinal malabsorption of vitamin B_{12} may coexist with congenital pernicious anemia in children as it does in adults. The diagnosis of congenital pernicious anemia is established by the criteria noted above. In these patients the normal absorption of B_{12} with intrinsic factor after therapy indicates that the selective malabsorption of B_{12} which was originally present was probably caused by B_{12} deficiency secondary to lack of intrinsic factor.[9]

A rare but well delineated genetic block in pyrimidine synthesis, transmitted as an autosomal recessive trait and clinically identifiable by the triad of infantile megaloblastic anemia, orotic aciduria and growth retardation has been documented. This anemia is refractory to vitamin B_{12} and folic acid. Oral administration of uridine bypasses the metabolic block and effectively alleviates the megaloblastosis, crystalluria and growth retardation.[10]

"Intestinal Steal Syndromes"

Under the term "intestinal steal syndromes," three general conditions related by a "competition" between the host and a parasite (or saprophyte) for available vitamin B_{12} are described. These include fish tapeworm infestation and anatomical variations in the intestinal tract due to natural disease processes, or occurring as the result of surgical procedures.

Fish Tapeworm Infestation

It is estimated that approximately twenty percent of the population of Finland is infested with the fish tapeworm *Diphyllobothrium latum (Dibothriocephalus latus)*, and a small percentage of these people manifest signs and symptoms of vitamin B_{12} deficiency. The mechanism whereby this worm utilizes or "steals" B_{12} has been studied; there are three principal means by which the worm might influence B_{12} uptake of the host:

1. It may destroy intrinsic factor or use it for its own B_{12} uptake.
2. It may split the B_{12}-intrinsic factor bond, prevent its formation, or use the entire complex.
3. It may inhibit the absorption process in the mucosa and/or the secretion of intrinsic factor.

The Schilling test with and without intrinsic factor was performed on worm carriers with and without anemia. After expulsion of the worm, another Schilling test was performed. In the worm carriers, increase in B_{12} excretion, when the test was performed with intrinsic factor, was only slight with the worm in situ. On the other hand, a significant increase in the Schilling values occurred after expulsion of the worm. This indicates that *D. latum* influences the B_{12} intrinsic-factor complex and/or has a blocking effect on the intestinal mucosa, resulting in inhibited B_{12} absorption.[11] Further studies using human gastric juice and hog intrinsic factor incubated with the worm, with and without added ^{60}Cobalt labeled B_{12}, indicated that the worm is capable of splitting the B_{12}-intrinsic-factor complex and also of impairing the B_{12} binding capacity of intrinsic factor.[12]

Intestinal Strictures, Fistulae and Diverticula

Megaloblastic changes in the marrow, response to vitamin B_{12} therapy and peripheral blood morphology similar to pernicious anemia have been described in cases of stricture in the lower ileum, strictures and ulceration of the jejunum, ileocolic fistula following tuberculous peritonitis, and in a variety of intestinal diverticula including those in the duodenum.[13,14] All of these patients respond to parenteral vitamin B_{12} therapy and recover spontaneously after corrective surgery. However, the mechanism involved is poorly understood. A decrease of absorptive surface does not appear to be involved in most cases, because absorption studies are usually normal. Bacterial "toxin" theories suggesting that bacteria in the diverticula or otherwise altered intestine produce some substance which inhibits absorption of B_{12} either by interfering with B_{12} or with mucosal cells remain unproven. In these cases abnormal small bowel flora may be presumed to be present (by other autopsy and dog studies). A pronounced increase of B_{12} absorption occurs with tetracycline administration, lending evidence to the concept that intestinal stasis causes bacterial overgrowth and direct bacterial interference with normal B_{12} utilization. Regional enteritis and sprue, not characterized by intestinal stasis, may demonstrate decreased B_{12} absorption which is not corrected with tetracycline.[15]

Blind Loop Syndrome

Certain surgical procedures performed on the gastrointestinal tract may leave a blind loop or be followed by intestinal stricture with subsequent development of macrocytosis and anemia which seems almost always to be due to B_{12} deficiency. The mechanism of defective B_{12} absorption involved in such blind-loop syndromes or iatrogenic strictures, etc., appears to be due to the presence of an abnormal intestinal flora, as in the case of strictures and diverticula, and, like these, is corrected by tetracycline administration.[13]

The Effect of Subtotal Gastrectomy

It is interesting to note that in a large study of 292 patients with a 60% gastric resection and Billroth I or Polya type reanastomosis for benign ulcer, anemia resulted in 53 percent of the cases (hemoglobin levels less than 13.6 gm/100 ml in males and less than 11.6 gm percent in females). Iron deficiency was noted in 44 percent of these patients and was unassociated with other causes of anemia in 55 of the 292 patients. There was associated morphologic evidence of B_{12} and/or folate deficiency in 84 of the 292 patients. B_{12} deficiency was diagnosed in 20 percent (B_{12} levels less than 160 $\mu\mu$gm/ml and morphologic evidence). The incidence of this deficiency increased, becoming maximum six to eight years after surgery. Folate deficiency occurred in twenty-six patients (serum folate less than 6 mμg/ml and morphologic evidence), but there was no correlation between the time of surgery and the time the folate deficiency was diagnosed. The mechanisms of anemia are probably chronic subacute gastrointestinal hemorrhage and reduced iron absorption plus deficiency of gastric intrinsic factor in the first two types; the mechanism of the folate deficiency is not understood.[16]

Malabsorption Syndromes Resulting in Abnormal B_{12} Absorption

The common denominator of nontropical sprue, tropical sprue, celiac disease and idiopathic steatorrhea is impaired intestinal absorption of various dietary substances. The etiology of these syndromes remains obscure but all may be included in the term "malabsorption syndrome." Secondary forms of malabsorption such as bowel resection, the "blind-loop syndrome," lymphosarcomas and intestinal lipodystrophy show gross pathological changes.

Schilling tests reveal decreased vitamin B_{12} absorption in both primary and secondary types which is not improved when done with intrinsic factor.[17]

Neomycin has been implicated in a malabsorption syndrome very similar to nontropical sprue. Patients studied with this condition show a decrease of 20-60% in Schilling test urinary excretion values, but these do not reach the low levels of absorption of pernicious anemia or more serious malabsorption syndromes.

Generally speaking, Addisonian pernicious anemia can be separated from megaloblastic anemias due to malabsorption by doing the Schilling test with and without intrinsic factor, addition of intrinsic factor failing to correct inadequate B_{12} absorption in the malabsorption syndromes, whereas absorption is normal in pernicious anemia when intrinsic factor is given.

It is important to be sure of the quality of the intrinsic factor used when doing Schilling tests in such studies. Intrinsic factor preparations of poor quality have been known to affect the results of the test when they are performed using intrinsic factor.

Faulty B_{12} Absorption Secondary to Deficiencies

Vitamin B_{12} Deficiency

Vitamin B_{12} deficiency due to intestinal malabsorption may result in gastric atrophy and loss of intrinsic factor formation. In such cases, if the damage has not progressed too far, reversal of gastric damage and return of intrinsic factor secretion may result from vitamin replacement therapy. Evidence suggests that secondary intestinal malabsorption of B_{12} is not rare in pernicious anemia and results from deficiency of the vitamin. A vicious cycle is thus set up.[18] This was demonstrated in a Hindu immigrant to this country who ate no meat. B_{12} absorption was shown to be defective by the Schilling test and failure to respond to oral B_{12}. The gastric juice contained abundant intrinsic factor at a time when he could not absorb B_{12}. With parenteral B_{12} therapy, the defective absorption of vitamin B_{12} disappeared. This "vegans syndrome" demonstrates the vicious cycle; absence of B_{12} damages the mucosa to the point where it fails to absorb B_{12}, at which time dietary B_{12} intake is of no value.[19]

Folate Deficiency

The effect of folate on B_{12} absorption has long been debated. Studies on patients with megaloblastic anemia of pregnancy show low serum folate levels in 83 percent (also decreased in 26 percent of nonanemic patients in their ninth month). Assays of vitamin B_{12} were decreased in 71 percent of anemic patients and in 46 percent of nonanemic patients in the ninth month of pregnancy.[20,21] Patients have been described with megaloblastic anemia associated with low serum folate levels and normal or borderline low serum B_{12} levels, but the Schilling test values proved that these patients did not have pernicious anemia. After treatment with folic acid the B_{12} values spontaneously returned to normal, thereby ruling out pernicious anemia. Perhaps folic acid is directly involved in B_{12} absorption, a number of folate-deficient patients having shown abnormal Schilling tests with and without intrinsic factor. Two such patients had normal B_{12} absorption following treatment with folic acid.[22] As is well known, folic acid therapy will temporarily correct the defect in nucleoprotein metabolism in pernicious anemia, but relapse eventually occurs unless B_{12} therapy is instituted.[23]

Iron Deficiency

Patients with iron-deficient normocytic anemia occasionally have associated vitamin B_{12} deficiency. In thirteen patients with this condition treated solely with iron, serum B_{12} levels spontaneously returned to normal within ten weeks. The suggested explanation is that B_{12} levels were restored when B_{12} absorption was corrected by iron therapy. It was also noted that ten of these thirteen patients with B_{12} deficiency had no free acid in the gastric contents after histamine stimulation. Such patients could be examples of incipient pernicious anemia. However, if the B_{12} deficiency in these patients were due to increased intrinsic factor secondary to chronic atrophic gastritis, then this decrease must be reversible, since the serum B_{12} levels increased after iron therapy, which they do not do in pernicious anemia.[24]

Vitamin C Deficiency

Vitamin C deficiency may be related to

megaloblastic anemia. If plasma levels of vitamin C are decreased and if ascorbic acid is given, reticulocytosis and improvement in the anemia may occur. This alteration in ascorbic acid metabolism may reflect changes in redox potentials associated with B_{12} deficiency. Vitamin C also plays a prominent role in maintaining the folic acid coenzymes in the reduced or active state, thus influencing folate metabolism and thereby perhaps influencing B_{12} absorption.[23,25]

Protein Malnutrition

Studies on rhesus monkeys made hypoalbuminemic to stimulate low protein states showed markedly decreased absorption of ^{58}Cobalt-labeled B_{12} which was completely corrected with protein repletion. This suggests damage to the intestinal mucosa and perhaps a decrease in intrinsic factor production from protein depletion which may be responsible for the decreased vitamin absorption.[26]

Effect of Drugs on B_{12} Absorption

Anticonvulsant Drugs

Some patients develop megaloblastic anemia while on anticonvulsant drugs. The majority of these cases respond to folate therapy, but occasional patients respond to B_{12} alone. Evidence of some disturbance in folate metabolism can be detected in the majority of epileptics treated with anticonvulsants. It is suggested that a functional change occurs in the intestinal wall in some patients taking anticonvulsant drugs and that this change may result in a relative defect in B_{12} absorption sufficient to produce a deficiency. Drugs implicated include Primidone, barbiturates, Phenytoin, phenobarbitone, dilantin, and Mysoline.[27,25,28]

Paraaminosalicylic Acid

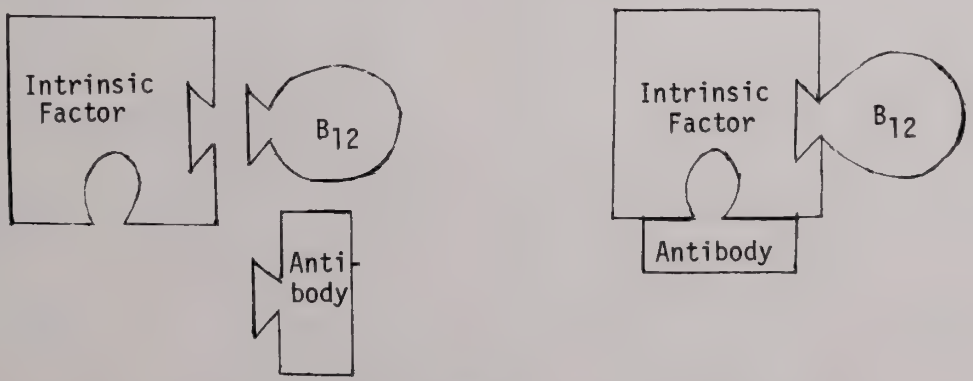
Patients taking paraaminosalicylic acid who do not have pernicious anemia may have abnormal Schilling tests which do not correct with intrinsic factor. Schilling test values after discontinuing the paraaminosalicylic acid, even without intrinsic factor, were normal. The excretion values of B_{12} in patients on paraaminosalicylic acid are diminished five to seven times. The mechanism is thought to be due to a malabsorption of B_{12} in the small intestine.[29]

Colchicine

Orally administered colchicine may affect vitamin B_{12} absorption. Studies show that this inhibition of absorption is greatest when the colchicine is directly instilled into the ileum, suggesting an induced defect of the ileal mucosa which is reversed when the drug is discontinued.[30]

Immunologic Factors in Vitamin B_{12} Malabsorption

More than 50 percent of all patients with adult type Addisonian pernicious anemia have circulating antibody to intrinsic factor, measurable either as antibody which blocks the ability of B_{12} to attach to intrinsic factor (blocking antibody), or as an antibody which combines with intrinsic factor in such a manner as to allow precipitation of the complex (precipitable antibody), or both.[31]



Figure

Blocking antibody-blocks B_{12} binding to intrinsic factor.

Precipitating antibody-binds to free intrinsic factor and also to intrinsic factor-B_{12} complex.[32]

About ninety percent of patients tested have antibodies to parietal cells, and about fifty percent have antibodies directed against the thyroid gland. The high incidence of antibodies in patients with pernicious anemia in combination with histologic features of chronic inflammation and atrophic gastritis suggests an autoimmune factor. This is partly substantiated by the high incidence of thyroiditis and myxedema in patients with pernicious anemia. However, these antibodies have not yet been shown to be harmful to gastric mucosa. The precipitating antibody has been demonstrated in the saliva of a patient with pernicious anemia and identified as an IgA immunoglobulin.[33,34] In a series of eighteen patients treated with prednisone, seven showed an increase in intrinsic factor production sufficient for normal B_{12} absorption. After steroid therapy normal gastric glands containing parietal cells were seen in atrophic mucosa in nine of the eighteen patients. The effect of steroids on gastric function and structure was in part found independent of the effects of gastric antibodies and may be a secondary phenomenon.[35]

Summary

A variety of conditions are discussed which result in decreased absorption of vitamin B_{12}. Included are classical Addisonian pernicious anemia, congenital defects of vitamin B_{12} absorption, parasitic conditions, malabsorption syndromes, deficiency states, drug interactions, and immunologic aspects related to B_{12} absorption. A patient is presented who demonstrates a defect in vitamin B_{12} absorption corrected with oral administration of folic acid and iron.

Book Reviews

Books are men of higher stature, and the only men that speak aloud for future times to hear.—E. B. Browning

1967-68 COLLECTED PAPERS IN MEDICINE AND SURGERY FROM THE MAYO CLINIC AND THE MAYO FOUNDATION. Volume 59. Two volumes $46.00. Singly $25.00. 511 and 578 pages. W. B. Saunders, Philadelphia, 1968.

This distillation of the awesome collection of papers published in one 12-month period by the Mayo Clinic staff will provide the reader with hours of instruction in many fields of medicine and surgery. The tab is high, but some papers alone are worth the price of the two volumes. For instance, McGoon's Olympian and total survey of cardiac surgery, condensing into one article the two that appeared last year in the New England Journal of Medicine, must be required reading for all cardiologists, though this reviewer cannot accept all of McGoon's "A" ratings for cardiac surgical conditions.

With this high praise McGoon will forgive an editorial correction: two ductuses do not make a couple of ducti. "Fibromuscular dysplasia and other uncommon diseases of the cervical carotid artery: angiographic aspects," by Houser and Baker is based upon more than 5000 cerebral angiograms and concerns 28 cases of non-atheromatous irregularities. Of these, 16 were fibromuscular dysplasia. The authors call attention to iatrogenic carotid artery disease following angiography. No therapy is discussed.

Aside from libraries, the natural audience for and purchasers of these volumes are the alumni of Mayo fellows. The books do offer a ready answer to most questions, such as: "How did the Mayo Clinic do it back in 67-68?"

R. Berman, M.D.
Minneapolis, Minnesota

BRAY'S CLINICAL LABORATORY METHODS, revised seventh edition by John D. Bauer, M.D., Philip G. Ackerman, Ph.D., and Gelson Toro, Ph.D. The C. V. Mosby Company, St. Louis, Missouri, 1968. Color plates 16. Pages 721. Appendix pages 3. Price $14.85.

The revised seventh edition is practically a new book. Drs. Bauer, Ackerman and Toro have updated the text, added new illustrations, and arranged the subjects in a logical order. Yet there are deficiencies. Iron metabolism, for instance, is too briefly discussed, and no mention is made of the iron-ascorbic acid chelation mechanism. The immunologic aspects of pernicious anemia are not discussed. The color plate "3" of the Friedman test is superfluous since this test has been replaced by more sensitive laboratory methods.

Though the term "pyknocyte" applied to the erythcocytes shown in Figure 4-15 may be acceptable, the cells presented in Figure 4-19 are not true "poikilocytes" but are examples of drying and staining artefacts. While the pathologic erythrocyte shown in Figure 4-22 is interesting, the concept however, that atypical or incomplete nuclear disappearance may leave a remnant of the nuclear membrane, forming a Cabot ring, is not valid (page 133).

The chapter on "Blood groups, blood typing and crossmatching" is one of the best presentations of these subjects I have encountered in clinical laboratory books. The chapters on clinical chemistry, serology, virology, parasitology, mycology and toxicology are well done.

Though the book has shortcomings they do not outweigh the many good features of the work. It is thus recommended to residents in clinical pathology, medical students, and medical technologists.

Emil Maro Schleicher, Ph.D.
Minneapolis, Minnesota

ATLAS OF EAR SURGERY, William H. Saunders, M.D. and Michael M. Paparella, M.D., Editors: C. V. Mosby Company, 1968; 363 pages. Price: $27.50.

This is a timely publication containing up-to-date information, which fills a gap in the library of the otolaryngologist. Operative procedures on otosclerotic deafness, fenestration, stapedectomy), reconstructive middle ear and mastoid surgery (tympanoplasty) are fully covered in detail.

The authors have also included all the essential operations in tumors, cosmetic, and reconstructive surgery of the ear. A section is devoted to the facial nerve surgery, and also the surgical treatment of Meniere's disease.

The print is of first quality; the illustrations are clear and artistic. The authors have magnificently accomplished a description of the operations precisely, briefly, step by step, with a special emphasis on the surgical technique.

They should be congratulated for this fine contribution. It is a reading must for every graduate student in otolaryngology and maxillo-facial surgery.

Ekrem Gozum, M.D.

Help the Needy!

This patient may appear to "have everything" but, like so many people getting along in years, she may well be in need—*medically*. Though there is no evidence of organic disease, she does have symptoms (fatigue, vague aches and pains, malaise) that may be indicative of—

a need to maintain anabolic balance... to counteract declining gonadal hormone secretion and forestall premature degenerative changes related to estrogen deficiency;

a need for mood elevation... to impart a gentle emotional uplift;

a need for nutritional supplementation... to compensate for the poor eating habits and subsequent dietary insufficiency of so many older people.

For these needs, consider MEDIATRIC for your next "needy" patient... medically.

MEDIATRIC provides specific agents to fulfill a need in the three areas:

1. **Gonadal steroids** [PREMARIN® (conjugated estrogens-equine), an orally active, natural estrogen, and methyltestosterone] for physiologic and metabolic benefits.
2. **Methamphetamine** to provide gentle elevation of mood.
3. **Nutritional supplements** specially selected to meet the requirements of the elderly individual.

Mediatric®

tablets • capsules • liquid

Steroid-nutritional compound

	Each MEDIATRIC® Tablet or Capsule contains:	Each 15 cc. (3 teaspoonfuls) of MEDIATRIC® Liquid contains:
Conjugated estrogens-equine (PREMARIN®)	0.25 mg.	0.25 mg.
Methyltestosterone	2.5 mg.	2.5 mg.
Methamphetamine HCl	1.0 mg.	1.0 mg.
Cyanocobalamin	2.5 mcg.	1.5 mcg.
Intrinsic factor concentrate	8.0 mg.	–
Thiamine HCl	–	5.0 mg.
Thiamine mononitrate	10.0 mg.	–
Riboflavin	5.0 mg.	–
Niacinamide	50.0 mg.	–
Pyridoxine HCl	3.0 mg.	–
Calcium pantothenate	20.0 mg.	–
Ferrous sulfate exsic.	30.0 mg.	–
Ascorbic acid	100.0 mg.	–
		Contains 15% alcohol† † Some Loss Unavoidable.

Contraindication: Carcinoma of the prostate, due to methyltestosterone component.

Warning: Some patients with pernicious anemia may not respond to treatment with the Tablets or Capsules, nor is cessation of response predictable. Periodic examinations and laboratory studies of pernicious anemia patients are essential and recommended.

Side Effects: In addition to withdrawal bleeding, breast tenderness or hirsutism may occur.

Suggested Dosages: *Male and female*—1 Tablet or Capsule, or 3 teaspoonfuls Liquid, daily or as required.

In the female: To avoid continuous stimulation of breast and uterus, cyclic therapy is recommended (3 week regimen with 1 week rest period—Withdrawal bleeding may occur during this 1 week rest period).
In the male: A careful check should be made on the status of the prostate gland when therapy is given for protracted intervals.

Supplied: No. 752—MEDIATRIC Tablets, in bottles of 100 and 1,000.
No. 252—MEDIATRIC Capsules, in bottles of 30, 100, and 1,000.
No. 910—MEDIATRIC Liquid, in bottles of 16 fluidounces.

Computer Medicine

Basic Concepts in Computer Science for Laboratory Physicians*

THE DIGITAL COMPUTER may have more impact on hospital services in the next decade than any other scientific instrument. Hospital administrators are now aware of the advantages of using digital computers for cost accounting, communication, and inventory control; but until now, physicians have not come into contact with the digital computer.

Uses of Computers in Hospitals

Nevertheless, digital computers have some applications in the hospital setting. Today, computerized patient records, pharmacy systems, outpatient appointment systems, and clinical and research laboratory systems are being developed in many institutions. The purpose of this paper is to acquaint the hospital or laboratory physician with certain basic concepts that are fundamental to understanding and applying the digital computer to hospital work.

General Purpose Computers

Presently, over one hundred different general-purpose digital computers flood the market, their purchase price ranging from $6,000 to over $10,000,000. Every year use of the computer increases; it is becoming part of our everyday existence. The tasks these computers can perform are too numerous to mention; but the three fundamental types of application are business data processing, general scientific computing, and real-time, on-line control.

Computer Hardware Organization

The operational hardware system of the digital computer consists of a central processing unit and certain peripheral devices. Regardless of their application, all general purpose digital computer systems are similarly organized (Figure).

I am sure you realize that the design of these five basic sections varies from one machine to another. These differences in design enable certain computers to perform specific applications better than other computers and also contribute to their differential in price. Before we proceed, let's spend a few moments describing in greater detail the five basic sections of a computer.

Input Operation

When a computer analyst is describing an input operation, he is usually referring to data coming from an external device. Card readers, magnetic tape units or, in the case of laboratory, an on-line auto-analyzer may bring in this data. Typically, input data is transferred to the computer's memory via a temporary input/output register and the computer's accumulator. This transfer operation takes place under the guidance of the computer's control unit.

Control Unit

The control unit is the logical complex that determines what operation is performed and when; it has built into it certain logical operations that it can perform. The computer is capable of performing only those operations previously built into it. The instruction repertoire is a list of commands which can be used to make up a program for the computer. On our basic block diagram, the data from an external device can be stored under program control by using the computer's store command. This data will be placed in the computer's memory until it is needed for processing.

---

*This paper was presented at the Symposium of the use of the Digital Computer in the hospital laboratory sponsored by the Minnesota Society of Clinical Pathologists at the Minnesota State Medical Association, Annual Meeting in Rochester, Minnesota on May 13, 1968.

Memory

Memory is the principal element of the computer. The cost and speed of its memory largely govern the cost and speed of the computer. The memory stores the program to be executed; it also stores input data until it is needed for processing, intermediate results during computation, and final results until they are needed for output. The memory stores its contents typically in the form of words. The word generally consists of from one to six characters depending upon the computer.

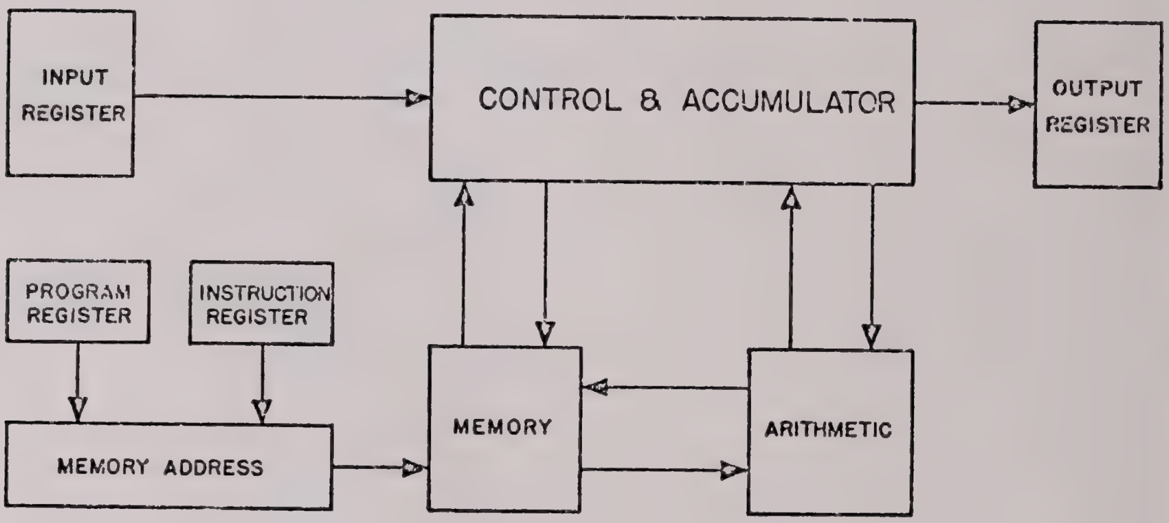
Word Size

When various manufacturers describe their products they typically refer to word size. This is the number of bits in a memory location. If six bits are necessary to represent a character, then a 12-bit machine would have the capability of representing two characters per word.

Memory Size

Another term frequently quoted by manufacturers is memory size. This is usually represented by two numbers, the smaller of which

Organization of a Digital Computer



Our basic block diagram consists of five basic sections of operation:

(1) input

(2) control

(3) memory

(4) arithmetic

(5) output

Figure

represents the number of words of storage provided by the manufacturer in the basic system, and the larger number representing the maximum expanded size of the computer. Thus, a machine specified as 4K expandable to 32K, has 4096 words of memory provided in the basic system which may be expanded to 32,768 words.

Cycle Time

Another term associated with the memory is cycle time, the time required to fetch a word from memory and then write it back. Typical third generation computers operate in the range from 700 nanoseconds through two microseconds.

Direct Memory Access

Many computers on the market today offer an option called direct memory access. This feature, referred to as DMA, allows an input/output peripheral device to put data directly into or take data directly from core memory. This type of option facilitates high speed data transfers and relieves the computer's control unit to perform other tasks.

Arithmetic Unit

The basic block diagram indicates a section labeled "Arithmetic Unit," which performs a specified arithmetic operation between a word contained in the computer's accumulator and the word fetched from memory. This section also contains the digital logic which has been prewired into the computer. On command, it will take two numbers and manipulate them according to instruction. It sometimes multiplies by successive adding and sometimes subtracts by complementing and then adding, always performing its specialized functions under the guidance of the computer's control section.

Output

The final section on our basic block diagram is the output section, structured in similar fashion to the input section and allowing us to obtain the calculated results that have been performed on the input data. A variety of external devices may be connected to the input and output sections of the central processor. These external devices are referred to as peripheral equipment and operate at a much slower speed than the central processor unit. The peripheral devices, together with the central processor, compose an operational hardware system. The choice of peripheral devices that are used on a system depends upon the operational task to be performed. Examples of common types of peripheral devices appear in Table 1.

Peripheral Equipment

Typewriters

The I/0 typewriter is an input/output device which operates as a normal typewriter with the additional feature that the information typed from the keyboard is entered into the computer. The computer is also able to send output data to the typewriter which will automatically print it. This is a low-speed device, the rate at which data can be put in depending on the typing speed of the individual. This conversation device is used to make minor programming changes or to initiate certain programs. When large quantities of data are involved, it is usually more efficient and economical to transfer this information via punched cards, paper tape or magnetic tape, as the system can absorb these at its own rapid rate.

Tape

Punched tape is used extensively as an input medium in general purpose digital computers and in some business data processors. Punched tape equipment typically has a cost and speed advantage over card equipment; however, its format is not quite as flexible as card equipment.

Punched Cards

Punched card equipment is used to read or punch information onto a 3¼ × 7⅜ card commonly referred to as an IBM card. Card equipment is used extensively in data processing type applications and offers the degree of flexibility necessary in this field.

Magnetic Tape

Digital magnetic tape has become the traditional mass storage medium of many data electronic data processors. Data transfer rate is a major criterion for magnetic tape users. With high speed equipment, data transfer rates of up to 120,000 characters per second may be achieved. This device is a good medium for putting in large blocks of data or storing large volumes of historical or audit trail information. However, the access time, or the time required to find one specific piece of information on the magnetic tape, can vary from over 10 seconds to one thousandth of a second, depending upon where the specific piece of information is stored on 2400 foot rolls of tape.

Rotating Mass Memories

Rotating mass memories are devices that have a thin magnetic coding applied to a drum or disk. This unit is rotated past magnetic heads that are used to read or write on the surface. By this technique, access time in the order of milliseconds can be achieved. This random access type of device is typically used in real-time systems where there is normally a need for storing a large amount of data with the ability to retrieve specific items at a rapid rate.

In a clinical laboratory system, a disk or a drum would be used to store the patient file, which could be updated at a high rate as input results are obtained from the laboratory. Rotating memories are sub-divided into disks or drums and are further divided according to whether the device has a fixed head or a movable mechanical positioning of the heads. The mechanical characteristics of this medium affect the access time and also the flexibility of the device.

Line Printer

The line printer is an output device used to print rapidly large volumes of data. Printers that are available today will print 132 column lines at a rate of from 150 lines to over 1200 lines per minute. Special Analog/Digital equipment, communications equipment, and CRT display units are also available as peripheral equipment.

Software Building Blocks

We shall begin our discussion of software by examining some of the basic building blocks used by the programmer in putting together a system program (Table 2).

TABLE 2
Software Building Blocks

1. Machine Language Coding
2. Assembly Language
3. Procedure-Oriented Languages
    COBOL
    FORTRAN
    PL/I
4. Utility Routines
5. Operating Systems

Machine Language Coding

Most basic of these blocks is machine language coding. While all internal operations of a computer are initiated by machine-recognizable instructions, it is rare to write a program in machine language. The chief use of actual machine language coding is in debugging when a programmer inserts a small routine directly into the machine to patch his program. This can be useful on certain computers and is a valuable tool to an experienced programmer. However, even this practice is being replaced by symbolic, debugging software.

Assembly Language

Probably the most widely used software language today is assembly language, in which a programmer has access to all machine facilities and yet is relieved of most of the clerical tasks. The programmer writes instructions in a symbolic form which has more significance to him than a string of numbers.

Many assembly languages extend the power of the programmer by providing more sophisticated features, such as the macro instruction which is coded by the programmer very much like any other imperative statement. Its purpose is not to generate a single machine language instruction but to perform a higher level task which takes several instructions. Both machine language coding and assembly language programming are languages which require the programmer to be knowledgable in the characteristics of the computer. We shall now talk about some higher level languages which are procedure-oriented and do not require such an intimate knowledge of the computer hardware.

Procedure-Oriented Language

The first of these, COBOL, which stands for Common Business Oriented Language, is a major procedure-oriented language developed for business applications. It has evolved through the efforts of computer manufacturers, the Department of Defense and other organizations, and is designed to be a machine-independent language: that is, its syntax and vocabulary are not dependent upon pecularities of any particular computer but reflect the logic commonly encountered in business data processing.

Because of its English-like appearance, COBOL is self-documenting to a greater extent than machine-oriented programs. A major criticism of COBOL is that it does not use the hardware as efficiently as an experienced programmer who uses an assembly language. More storage is used and running time is longer. In the past, these objections were valid but are now being remedied to some extent as new compilers are written with the experience of past errors in mind.

Formula Translation

Fortran, an abbreviation of *FORmula TRANslation,* is a procedure-oriented language developed for use in scientific problem-solving and at this time is the most widely used procedure-oriented language. It is largely machine-independent; but because of the lack of standardization in its early development some adjustments are necessary to move from one computer to another.

PL/1

PL/1 is a new language designed for use on both data processing and scientific problems as well as for real-time and systems programming. It incorporates features found to be useful in previous languages such as COBOL and FORTRAN and takes into account new hardware features, such as mass storage and data communications.

Table 3 illustrates the instructing sequences required for coding the solution of an equation using machine language, assembly language, and FORTRAN.

There are other procedure-oriented languages, each with its own characteristics. Most of these languages have been developed for special applications. Therefore we will omit them here.

Utility Routines

Most software systems include programs that perform miscellaneous day-to-day functions. Some of these programs offer only minor conveniences while others are essential to daily operations. These routines are sometimes referred to as utility or service routines. Commonly used utility routines are generated to sort and to merge programs.

TABLE 3

Language Comparison

The following instruction sequences represent the coding for the solution of the general equation

$$G = A + B\,(C-D) + E/F$$

first in machine language, then assembly language and finally in higher level language (FORTRAN).

I. Machine Language

```
8005
3006
7007
8003
8004
5002
A001
A007
7007
```

II. Assembly Language

```
LDW E    Divide E by F
DVI F
STW G    Save Intermediate Result
LDW C
SUB D    Form C-D
MPY B    Multiply By B
ADD A    Add A
ADD G    Add E/F
STW G    Save Result in G
```

III. Higher Level Language (FORTRAN)

```
G = A + B * (C-D) + E/F
```

Another form of utility routine is the linkage editor which combines several segments into one routine and permits the repeated use of subroutines.

The most frequently used utility programs are the type which facilitate routine data handling. These include inquiries to auxiliary storage devices, tape copying and editing, and media conversions such as card to tape, tape to card, tape to print, etc.

Operating Systems

To the user of a data processing system, a measure of performance is the internal operating speed of a machine. This feature tells the user how fast a particular job can be processed once a run is started, but it does not take into account such variables as set-up time and delays while awaiting operating instructions. As machine speeds have increased, such overhead operations have taken on an increasingly important segment of time. To counteract degradation of system performance by manual intervention, operating systems have come into wider use, the general purpose of which is to automate manual procedures and at the same time provide a standard and helpful machine environment.

Most operating systems have three major tasks: language translation, job control and data control. Operating systems can accept properly identified programs in several languages and call on the proper translator to reduce the statement to some form of machine language.

Some advanced operating systems include multi-program features which provide significant time-saving advantages. With this capability two or more tasks can be processed concurrently.

A good operating system can be an effective means of multiplying programmer productivity, standardizing machine operations, increasing system throughput, and reducing the chances of undetected errors. A price must be paid for these advantages, however, because operating systems occupy storage space. In the case of advanced system, the storage used can be sizeable. Frequently a larger machine will be needed to accommodate the operating system. These alternatives present trade-off decisions which must be made by the prospective user.

Summary

The digital computer may be used in the hospital setting in three fundamental areas of application: business data processing, general scientific computing, and real-time, on-line control. We have summarized the five basic sections of operation in the organization of computer hardware. Basic definitions of input, control, memory, arithmetic and output have been presented. Various types of peripheral devices and equipment available to expand the capability of the central processing unit are outlined.

In our discussion of computer system software we have taken a brief look at some of the major building blocks available for software systems. We have looked at assembly language, and the various higher level languages or compilers. We have also examined some of the features of operating systems and utility programs. Proper selection of these and other building blocks is essential to the successful computer solution to everyday problems. Each application must be investigated on its own merit to insure that the correct techniques are used for that particular situation.

†Associate Pathologist, Hennepin County General Hospital.

Jumping to Conclusions

Mrs. White was taken suddenly ill in the night, and the new doctor was called because he was the nearest available.

After a look at the patient, the doctor stepped outside the sickroom to ask Mr. White for a corkscrew. Given the tool, he disappeared, but several minutes later was back, demanding a pair of pliers.

Again he disappeared into the room of the moaning patient, only to call out again, "A chisel and a mallet, quickly."

White could stand it no longer: "What ails her, Doc, for gosh sakes?"

"Don't know yet," was the reply. "Can't get my instrument bag open."

Diversified Numeric Applications On-Line Clinical Laboratory System

MODERN HOSPITAL clinical laboratories do an ever increasing number of chemical tests. With the advent of intensive care units and other specialized treatment areas, a need will develop for continuous chemical and electrical monitoring. Many instruments in today's laboratory are automated and produce so many results that they tend to overwhelm the physician. The answer to this plight is two-fold. First, a laboratory must produce a written document so that the physician can recognize abnormal quantitative trends; second, laboratory information must be delivered promptly to the patient's bedside and the physician's hands. The on-line digital computer offers satisfactory solutions to these problems.

Changes in Computers

The computer industry has undergone revolutionary changes over the past few years. These have particular significance to physicians. Newer, faster, more powerful computers have recently become available, at a fraction of previous costs. Because of the use of solid state, integrated circuit logic and new production techniques, manufacturers can reduce costs. As a result, for each dollar spent the computer user receives more computing power per dollar than he would have had a few years ago. Now, a clinical laboratory in a community hospital with 300 beds or more can have its own data processing system designed to fit its needs. This paper describes a low cost data processing system designed specifically for the hospital clinical laboratory.

Basic Design Criteria

The following basic design criteria were considered important if this system was to help the typical working clinical laboratory and not be merely an expensive experiment.

1. Laboratory personnel must be able to operate the system. It should require no skilled operators or programmers.
2. The system must function as a working tool of the laboratory technologist—much like any other instrument used in the laboratory. The system should not appear to be remote and mysterious.
3. The system must be such that technologists have no direct contact with the basic computer. They should work with peripheral devices so designed as to fit in with existing procedures.
4. The system must be inexpensive. The increased productivity and improved quality of laboratory work must justify the cost.
5. The system must blend with existing routines and not require any major changes in laboratory procedures.
6. The system must be simple and foolproof to use and convenient enough so that laboratory technologists readily accept it.
7. The system must, wherever possible, use the special abilities of the computer to improve the quality of laboratory work beyond that practical with manual techniques.
8. The system must operate 24 hours a day, seven days a week, for extended periods of time.
9. The system should have a 100% reliable backup procedure to handle the situation when part of the system fails.

On-Line Computer Capability

The above criteria can be met only with an on-line computer system, for, with such a system, the technologist can interact continuously with the computer much as he does with any instruments.

Though any computer system can detect human errors by analyzing the input data, only an on-line system can instantaneously notify

---

*This paper was presented at the symposium on the use of the digital computer in the hospital laboratory sponsored by the Minnesota Society of Clinical Pathologists at the Minnesota State Medical Association Annual Meeting in Rochester, Minnesota on May 13, 1968.

the responsible individual, so that corrective action can be taken immediately, thereby minimizing the entry of erroneous data into final test reports.

Figure 1 illustrates how the laboratory system is organized and how it relates to all laboratory sections. Included are a small low-cost general purpose digital computer; auxiliary random access mass memory; several terminals located throughout the laboratories; analog to digital interface equipment; and one or more printing devices. The computer or central processor, together with its random access auxiliary memory, performs all of the decision making, data processing, and information storage functions of the laboratory system.

Central computer and auxiliary memory are placed in an out of the way location and are never touched during normal operation. Terminal devices control the system through a simple pushbutton operation.

The on-line clinical laboratory system handles laboratory data for inpatients, outpatients and emergency patients. It also collects and organizes the billing data for the hospital administration.

The Diversified Numeric Applications system can serve all sections of the laboratory, including chemistry, hematology, bacteriology and urinalysis. All system functions are on-line and are always available for instantaneous execution. The system has built-in provision for communication with other hospital computers, and can be utilized to output reports to critical areas such as emergency rooms, outpatient clinics, or other associated hospitals.

Description of the System

The best way to explain how a system operates is to review the procedures involved in a typical day's use. The sequence of events described are those that take place in a typical hospital. Differences exist between hospitals but the system is flexible enough to be modified.

The Laboratory Request Entry Console

Usually laboratory personnel collect routine requests during the night and in the morning for the day's run. Early in the morning, the accumulated requests are entered into the computer system. This may be done in several

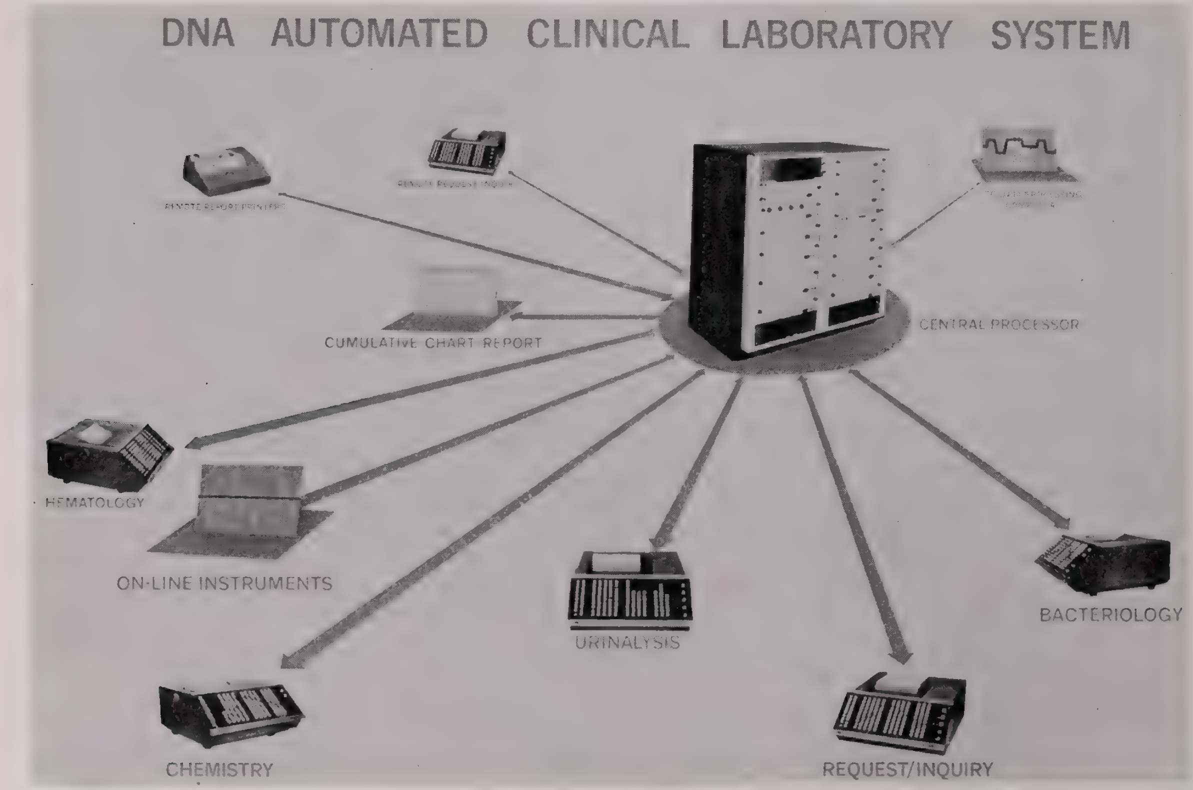

Fig. 1—Block Diagram

ways. The general case would be the one in which requests are brought to the laboratory on small request slips. Results are then entered into the computer through the Laboratory Request Entry Console (Figures 2 & 3).

Entering the Data

The procedure is to enter the patient number, ward or room number, plus a code number that corresponds to the particular tests requested. Miscellaneous codes are available to handle special cases like "No Charge." As the request data is entered, it is stored in the console to be verified. No data is transmitted to the computer until the technologist specifically requests transmission by depressing a button labeled "Enter Request." In other words, the person making the entries can visually verify the entire entry and can correct an error before entering data into the computer. After visual verification, the "Enter Request" button is depressed which sends the entire request message to the computer. The request is stored in the

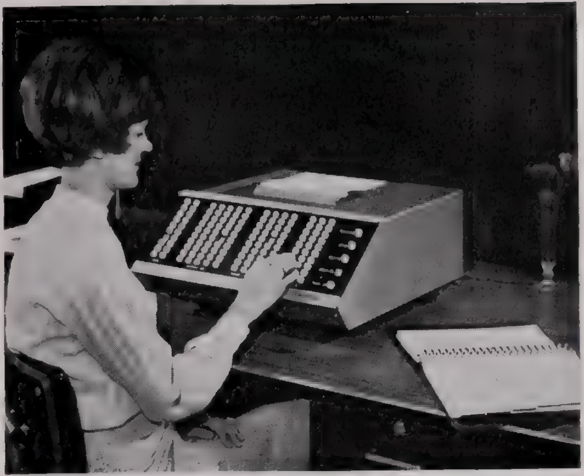

Fig. 2—This photograph illustrates how a DNA 20/20 request terminal is utilized to make rapid inquiries into the system. The operator merely enters the patient number and tests type and then depresses the "Inquire" button to obtain a seven-day historical summary report from a specific test service. This report will aid the physician in identifying abnormal trends. Similar DNA 20/20 consoles are utilized to input qualitative test data.

Fig. 4—Request Printout

Retrieval of Fixed Information

Notice that the first entry for a patient initiates a printout of the complete heading for that patient, including the patient's name, number, doctor, room number and other pertinent fixed information. An important feature of the system is that fixed patient data is not entered with each patient request. The computer retrieves from a file of all inpatient information stored in its auxiliary memory and updates it as patients are admitted to and discharged from the hospital. After the clerk enters the first test for a given patient she can request each additional test with a code number. The computer instantaneously replies to the entry by printing out a description of the requested tests. With this procedure, the computer can prepare an individual request summary for each patient. This can then be compared with the original request slips to assure validity.

The entry procedure can vary. For example, rather than entering all the requests centrally in the laboratory, request terminals can be located remotely at nursing stations to speed communications and minimize clerical work for laboratory personnel. Another variation would be the entry of test requests on punched cards or some other form of machine readable input.

Organization of Laboratory Activities

The next phase of the system's operation is organizing activities for the laboratory personnel. This is done by the computer. It analyzes test requests and prepares printed documents based upon this analysis. At his discretion, the laboratory director uses the master console to initiate preparation of the basic organizational reports, including the blood drawing lists, test worksheets, and specimen labels.

The Master Console

Before describing these reports let's consider the master console more carefully. The master console allows the laboratory director to completely control the operation of the computer system without performing any actions directly on the basic computer. This is an important point because the computer itself has a complex control panel designed to be used by experienced programmers. The master console, however, is a simple device; it provides the laboratory director control through a group of individually labeled function buttons. If the laboratory director wishes to prepare blood drawing lists and worksheets, he presses the buttons labeled, "Blood Drawing" and "Worksheet". The computer then proceeds to printout these reports on the high speed printer.

Blood Drawing Lists

The blood drawing list (Figure 5) contains patient name, number, room number or ward, and specimen number. The computer assigns specimen numbers and maintains an index correlating these numbers with patient numbers. In addition to blood drawing lists, the system simultaneously prepares specimen labels for each individual patient.

565010	Nyberg, Oscar V.	C0747
046033	Skillings, Clyde	C0935

Fig. 5—Blood Drawing List

Specimen Labels

The labels identify the specimen by patient number, name, date, specimen number and ward location or room number and also indicate the type of container to be used for each specimen. With computer-prepared blood drawing lists and specimen labels, blood drawing becomes a thoroughly organized and controlled activity. The computer also prints worksheets for each test to be performed.

Laboratory Worksheets

The worksheet (Figure 6) includes the test name and number, specimen number, patient name and number. Room is provided for writing in results where data is not transmitted directly from an instrument to the computer. Worksheets can be generated throughout the day—with each new sheet including only those tests requested since the printout of the last worksheet.

Entry of Test Results

All of these procedures precede the actual entry and storage of test results in the computer. The next phase of system operation concerns the gathering of test results by the computer for storage and processing.

Fig. 7—Test Result Keyboard Layout

*On-Line Auto-Analyzer®**

Test data is entered into the computer in two ways. First, certain instruments are connected directly to the computer. With digital output instruments data can be taken directly from the instrument. The technologist pushes a button which transmits the data to the computer where it is stored. With analog output instrument, the data first goes through an analog to digital converter and is then stored in the computer. With completely automatic instruments such as the auto-analyzer,® the technologist does not need to intervene once the instrument is loaded makes calculations, prints out results for inspec- with samples. The computer stores test data, tion. Finally results are ready for the completed patient report.

The Manual Test Result Console

In situations where it is either not possible or not desirable to interface an instrument directly to the computer, data is entered through the test result console, which is specially designed to provide a simple and reliable method for accurately entering test data into the system. The design of the console is similar to the request console (Figure 2), but the input keyboard layout is tailored to data entry (Figure 7).

Typically the technologist would enter a series of results for a given test, taken from the worksheet for that test. The keyboard of the terminal is designed to correspond to one line of the worksheet—which includes test number, specimen number and result. No data is transmitted to the computer until the technologist visually verifies that the right keys have been pressed and then pushes the button labeled "Enter & Reply." The entire message is then transmitted to the computer where several things occur practically instantaneously.

Verification of Results

First the data is checked against statistical limits to detect abnormal entries which might indicate either an operator error or a legitimate abnormal value. The computer also looks up the test name corresponding to the test number. A reply is instantaneously generated by the printer which is built into the result terminal (Figure 8).

The reply consists of the test number, the test name, specimen number, and the result. This print-out allows the technologist to verify the entry and to correct it if an error has been made. It also serves as a record for audit and control purposes. If a result exceeds certain preset limits, established for each type of test, the terminal prints a message to alarm the technologist of this fact.

Inquiry Potential

Throughout the day results are stored in the computer until all tests for a given patient are completed. However, at any time, inquiries can be made into the system, using the request console in order to obtain partial results for a given patient. Inquiries can be made either by patient's name or number. It is also possible to make inquiries directly from remote locations

by using request consoles located at nursing stations and other central points within the hospital.

Additional Reports from the Master Console

The laboratory director can request a variety of reports by using the master console. These reports include the worksheets and blood drawing lists already described. Other reports which can be requested include:

1. Auto-Analyzer Summary (Figure 9): a printout of all completed auto-analyzer results for verification purposes.
2. Unfinished request report: a report of all tests requested but not yet completed.
3. Floor Report (Figure 10): a list of test results by patient for all patients in a given ward or other physical area.
4. Statistical Reports (Figure 11): a summary of the total number of tests performed broken down by service.
5. Chart Report (Figure 12): a report of the current day's test results for a given patient.
6. Cumulative Chart Report: the results of all previous tests for the entire week, summarized on a daily basis.

The cumulative chart report is a major benefit of the system since an entire week's results are summarized on one sheet of paper and placed in the patient chart. This speeds up the interpretation of data by the physician and minimizes the possibility of losing individual results. Should a report be lost, an entire

week's report can be duplicated by the computer in seconds.

Growth Potential of the System

Although the system described is a stand-alone system operating entirely within the confines of the laboratory, it has been designed to facilitate two avenues of projected growth. First, the requirements of the laboratory are sure to change, and the modular design of the computer system accommodates these changes by allowing the simple addition of new instruments and new programs. Second, the system anticipates the growing importance of communications within the hospital and has adequate provision for handling a large number of communication terminals located outside of the laboratory for direct input of test requests and local printout of patient reports.

The Total Hospital Information System

Even more important, however, the system anticipates that other small computer systems will be installed in different areas of the hospital. These systems, like the laboratory system, will at first be independent. But at some future time, as more is learned about the information flows among the various hospital departments, these independent systems will be interconnected to form a total hospital information and communications network. This concept of a number of small computers interconnected to form a network is a new one, but a concept rapidly gaining acceptance as the most practical method by which small and medium-sized hospitals can commence upon a program of clinical and administrative automation on a realistic evolutionary basis.

Summary

The Diversified Numeric Applications Clinical Laboratory System is a low cost, 100% on-line, random access data processing system designed specifically for the clinical laboratory. DNA's exclusive functionally designed clinical laboratory data terminal permits complete operation of the system by existing laboratory personnel. Laboratory personnel interact with the system entirely through foolproof terminals and are never required to change tapes or perform any operation directly on the basic computer.

The Diversified Numeric Applications laboratory system is provided as a complete package that is customized to meet the needs of the particular laboratory. The DNA system package includes hardware, all laboratory application programs, documentation, training, systems installation and maintenance.

Social State Medicine

In the area of nutrition and health it would be relatively easy to produce economically in factories a "man chow" which would supposedly be the perfect food for the average man. This "man chow" idea is completely unrealistic. It will not work, because of the biochemical individuality of man.

The Food and Drug Administration, at least until very recently, has done some of its planning on the basis of the hypothetical average man and has sought to regulate the marketing of medicinal substances on this basis. This cannot work because of the hard facts of biochemical individuality. People do not react in a uniform manner, either to drugs or to nutritional factors.

Roger J. Williams, The Freeman, January 1969.

Two things we ought to learn from history: one, that we are not in ourselves superior to our fathers; another, that we are shamefully and monstrously inferior to them, if we do not advance beyond them.—T. Arnold

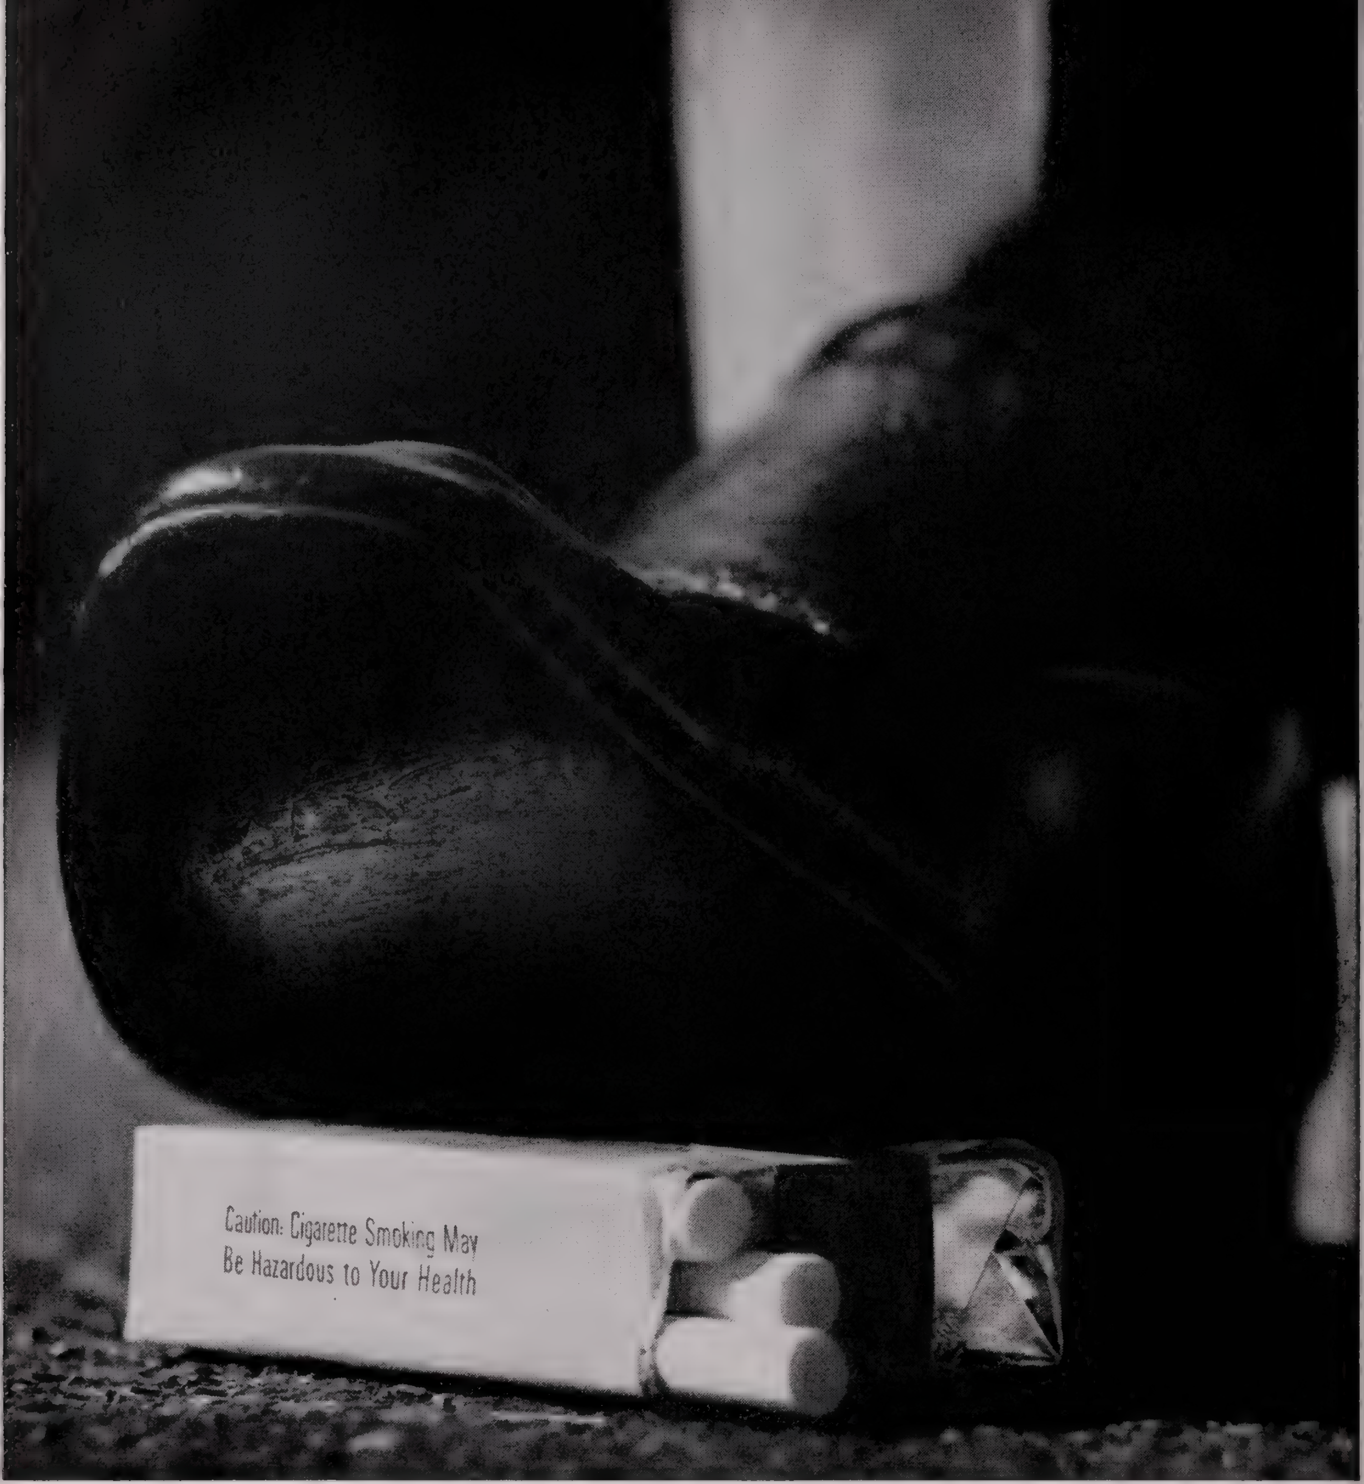
It is easier to make certain things legal than to make them legitimate.—Chamfort



Caution: Cigarette Smoking May
Be Hazardous to Your Health

If you give up cigarettes, you might gain a few pounds.

(And also a few years.)

The plain, unfiltered fact is that people who smoke cigarettes get lung cancer a lot more frequently than nonsmokers.

And lung cancer can finish you.

Before your time.

We'd rather have you stay alive and in good health.

Because even if you do gain a few pounds, you'll have the time to take them off.

GASTROENTEROLOGIC COMPLICATIONS OF ANTICOAGULANT THERAPY

Concomitant with the therapeutic use of anticoagulants "new diseases of medical progress" have developed, related to the physiologic and pathologic variability in humans. The major and most feared side effect has been hemorrhage.

"Manifestations of bleeding such as melena, hematemesis, and hematochezia may be harbingers of serious underlying disease." These complications may be sudden and demand immediate and appropriate therapy. To persist in anticoagulant therapy when a patient is bleeding into the intestinal lumen, intra-abdominal viscera, or rectus muscle may be disastrous; to discontinue anticoagulant therapy may invite new thromboembolic episodes. A list of complications associated with anticoagulant therapy is revealing.

The incidence of hemorrhage is reviewed in nine reported series. In non-hospitalized patients on anticoagulant therapy the incidence of hemorrhage is from 5 to 48%. Other reports vary from 2 to 10%. The incidence of major hemorrhage varies from 0.8 to 12%. Russek and Zohman stated that about 50% of 228 medical specialists observed serious hemorrhage following anticoagulant therapy for acute myocardial infarction.

Approximately 3 to 4% of patients on anticoagulant therapy have gastrointestinal bleeding. A questionnaire by Russek and Zohman revealed 30 reports of death due to exsanguination after gastrointestinal bleeding. Two of four patients with inoperable cancer of the stomach had hematemesis when taking anticoagulants. One woman is reported to have bled from peptic ulcer after taking dicumarol for thrombophlebitis. One should suspect malignancy in cases having gastrointestinal bleeding if the prothrombin time is in the therapeutic range.

Several authors reported lesions in the gastrointestinal tract that bled in patients who were on anticoagulants. The most common lesions that bled were peptic ulcer, hemorrhoids, cancer, diaphragmatic hernia, and diverticula. Lesions found included peptic ulcer and carcinoma of the colon. Nathan and Kimball received 1,867 replies to a questionnaire; 128 reported unsuspected tumor in patients who bled while on anticoagulants. Zweifler's series reported that seven of 12, who bled when the prothrombin activity was greater than

15%, had organic lesions; in the 12 with a prothrombin less than 15% no occult lesion was found.

Patients with T-tube drainage of the common duct are sensitive to oral anticoagulants and more apt to hemorrhage if pancreatic disease is present.

Bleeding into the bowel wall occurred in 63 cases; in the small bowel in 54 cases; in both the small and the large bowel, in five cases; and in the large bowel only, in three cases.

Most authors have stated that bleeding starts in the submucosal layer. Extension to the mucosa causes varying degrees of obstruction and blood in the lumen. Dissection toward the serosa results in decreased peristalsis and possible bleeding into the mesentery and peritoneal cavity, causing volvulus and obstruction. Onset may be gradual, accompanied by cramping pain, distention and vomiting. Bleeding may be also present in the skin, gums, urine and feces.

X-ray examination may reveal intra-intestinal and intramural hemorrhage, characteristic fluid level and obstruction. Blood may migrate to the flanks by following fascial planes.

Nonoperative medical regimens consist of I.V. fluids with small doses of vitamin K. These patients are often elderly and are a poor surgical risk because of arteriosclerotic disease. Thirty of 63 patients were managed successfully without surgery. Seven of 33 patients were explored for possible bowel viability; 33 had abdominal operations; 24 had resections, and two had bypass procedures. There were five postoperative deaths, three secondary to myocardial infarction. A fourth patient died eight days postoperatively from gangrene of the bowel at the site of the previous resection. The fifth patient, a 75-year-old male with three previous myocardial infarctions, died five days postoperatively. Autopsy revealed intramural hemorrhage extending from the small bowel to the sigmoid colon.

Each patient must be watched for continuing hemorrhage, unresolved obstruction, bowel perforation, or persistent symptoms which demand laparotomy.

Hemorrhage may be retroperitoneal, 12 cases being reported from the University of Pennsylvania, or intra-abdominal, involving the pancreas, ovarian cysts or adnexia, with massive accumulation of blood in the peritoneal cavity. Jaundice due to liver injury has been reported as the direct effect of anticoagulant drugs.

Complications resulting from anticoagulant therapy must be anticipated. The effects may be minor or major. Medical management may be adequate; but surgery may be imperative if intra-abdominal hemorrhage is not controlled. Gangrenous organs or bowel demand surgery which carries with it a high risk. Reports all seem to favor medical treatment when possible. This publication in the Mayo Clinic Procedures is most valuable to both internist and surgeon. The authors should be complimented on its presentation.

CONGENITAL HEART DISEASE—SURGICAL RESULTS

Surgical correction of many congenital heart defects can be carried out with a high degree of safety. Techniques of extracorporeal circulation, even for quite small children, are well standardized and accompanied by low risk. The pathologic anatomy of most congenital cardiac anomalies has been well described, and techniques for correction of the more common varieties can be expected to produce excellent results.

We have operated upon twenty-six patients for correction of various congenital cardiac anomalies. The pathology encountered is indicated in Table 1. Atrial septal defect, with or without partial anomalous venous return, was the most common lesion. Two highly unusual anomalies are also included in this group, namely "parachute mitral valve" and congenital diverticulum of the left ventricle. All of these patients were operated upon by open intracardiac techniques. Although one was quite elderly (i.e., atrial septal defect—age 76), most were children or young adults. Their ages ranged from 1½ years to 76 years; three were two years of age or younger at the time of surgery. There were no operative deaths and all twenty-six patients are currently alive and well.

Since the first ventricular septal defect was repaired in 1954 by cross circulation, great strides have been made in the safety with which open heart surgery can be accomplished. The techniques of extracorporeal circulation have undergone refinement to the extent that careful, deliberate repair is attended with low risk even in the very young patient. Heart block, air embolus, residual shunt and uncontrollable bleeding, which plagued the cardiac surgeon of a decade ago, are problems that can now largely be avoided. The more common congenital cardiac anomalies such as atrial septal defect, with or without partial anomalous venous returns, partial A-V canal, pulmonary stenosis, ventricular septal defect and tetralogy of Fallot can all be treated by safe, well standardized techniques with excellent results.

CAN BREAST CARCINOMA BE ANTICIPATED?

Potter et al. have analyzed a series of 110 cases upon whom biopsies had been done for benign lesions 16 to 20 years prior to the period of study. In this study they found that five times as many patients who had been biopsied for benign lesions developed carcinoma of the breast but that this had no relationship to the specific pathologic process in the benign biopsy. It did have, however, a relationship to the years at risk.

These findings support a recommendation that all women who have biopsies for a benign lesion of the breast should have periodic checkups since carcinoma develops with much higher frequency in these women.

Editor's Note: Perhaps it also suggests that adenomammectomy would be a desirable procedure for all biopsies.*

SONS OF ALCOHOLICS

To obtain indirect evidence regarding the personality of potential alcoholics, sons of alcoholic men were studied by a 36-item behavioral questionnaire constructed to measure personality traits common in alcoholics. Forty-one sons of alcoholics were compared with 123 matched controls by classroom teachers. Contrary to the hypothesis tested, sons of alcoholics were rated less personable and more overtly aggressive than the controls. The results were interpreted as showing a passive-aggressive personality preceding and possibly leading to alcoholism.

Blains

Exodus IX 8-11: And the Lord said unto Moses and unto Aaron, Take to you handfuls of ashes of the furnace, and let Moses sprinkle it toward heaven in the sight of the Pharaoh.

And it shall become small dust in all the land of Egypt, and shall be a boil breaking forth with blains upon man and upon beast, throughout all the land of Egypt.

And they took ashes of the furnace and stood before Pharaoh and Moses sprinkled it upward towards heaven; and it became a boil breaking forth with blains upon man and upon beast.

And the magicians could not stand before Moses because of the boils; for the boil was upon the magicians and upon all the Egyptians.

The Relationship of Neonatal Nutrition to Brain Growth*

HAROLD W. HERMANN, M.D.†
Evansville, Indiana

THIS MONOGRAPH presents in abbreviated form some recent discoveries in the relationship of neonatal nutrition to brain growth and development. Animal data will be given first, to be followed by a limited amount of information pertaining to the human.

Calculating Growth

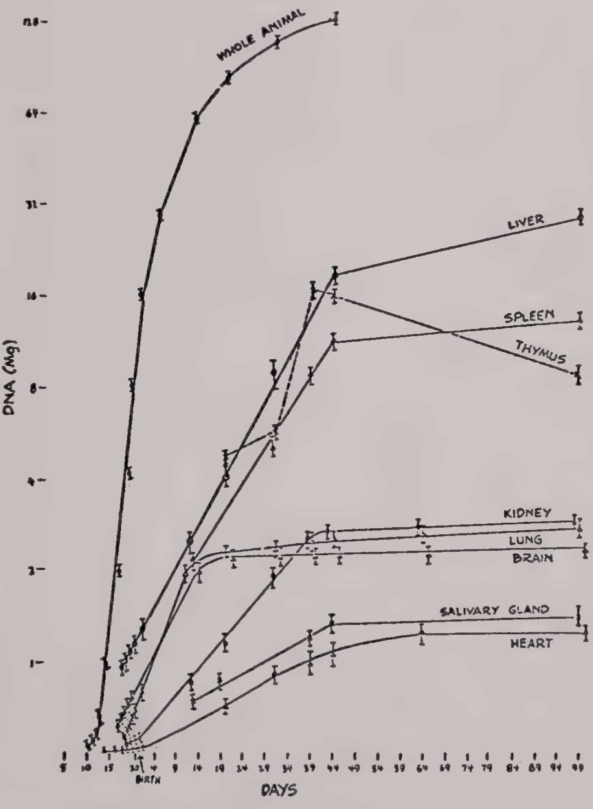
In 1962 Enesco and Leblond[1] published their findings that each diploid nucleus cell of the rat contains 6.2 micro-micrograms of deoxyribonucleic acid. It has since been determined that the amount of deoxyribonucleic acid per nucleus cell is species-constant. Therefore, the number of cells per organ for any species can be calculated at any point of growth and development upon determination of the total organdeoxyribonucleic acid.

$$\text{Cell number} = \text{number of nuclei (millions)} = \frac{\text{total organ deoxyribonucleic acid in mg.} \times 10^3}{6.2}$$

The weight per nucleus can then be determined by dividing the total organ weight by the number of nuclei.

$$\text{Cell weight estimate} = \frac{\text{total organ weight (gm.)} \times 10^3}{\text{number of nuclei } 10^6}$$

Winick and Noble[2] have shown that deoxyribonucleic acid in each body organ reaches a maximum early in development of the animal at a time characteristic for that organ and does not increase during further growth. Early prenatal growth in the rat proceeds entirely by cell division; the deoxyribonucleic acid, weight,



DNA (mg) during normal growth in the rat. Points represent mean values for at least ten animals or organs. I represents range.

*Quantitative Changes in Deoxyribonucleic Acid, Ribonucleic Acid, and Protein during Prenatal and Postnatal Growth in the Rat," Myron Winick and Adele Noble, Developmental Biology, Vol. 21, December, 1965.

and protein all increase proportionately with a constant cell size resulting. However, after birth, the rate of deoxyribonucleic acid synthesis (cell division) decreases at different times for various organs. Cell size increases with increased protein accumulation as the cell division rate decreases. More specifically, in the rat, growth from ten days after conception to maturity occurs in three phases: first, a rapid cell division with the cell size constant (period of deoxyribonucleic acid production only); second, an increase in cell size and cell number (period of deoxyribonucleic acid production and protein accumulation); and third, an increase in cell size only (period of protein accumulation only).

Maximum Growth

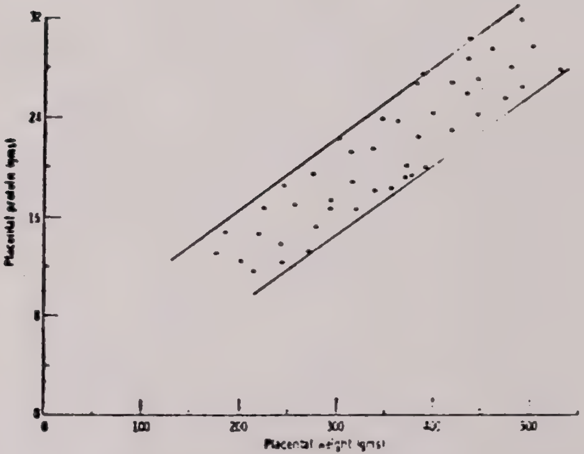
Winick and Noble have also shown that during the active period of growth in the rat deoxyribonucleic acid, ribonucleic acid, and protein increase at a specific rate for each organ for a constant period; growth stops when the total organ weight or protein reaches a constant (Figure 1). In rats the brain and lungs reach their maximum number of cells on day seventeen after birth. The other body organs continue to develop new cells until about the 42nd day of life.

Effect of Limiting Calories and Protein

It has been shown in the rat that limiting calories and protein during the first 21 days of life (period of organ development by cellular division) to about one half of normal requirements results in dwarfism with a permanent reduction of cell numbers (deoxyribonucleic acid) in all organs. Analysis of all organs shows a parallel reduction in the deoxyribonucleic acid, ribonucleic acid, and cell protein composition, and subsequent adequate nutritional feeding reveals these changes to be irreversible. A similar nutritional deprivation during only the second 21-day period of life (first three weeks postweaning) results in developmental retardation in both cell number and organ size in all organs except the brain and lungs, with a reduction in deoxyribonucleic acid, ribonucleic acid, and cell protein in these affected organs. These changes are also irreversible with subsequent full nutritional support. Finally, a 50% deprivation of calories and protein during the third 21-day period of life (after all cell division is completed) results in reduced cell size but no reduction in cell number. The cell size becomes normal with adequate subsequent nutrition.

Semistarvation During Gestation

Chow and Lee[3] have confirmed that the



Placental protein versus placental weight.

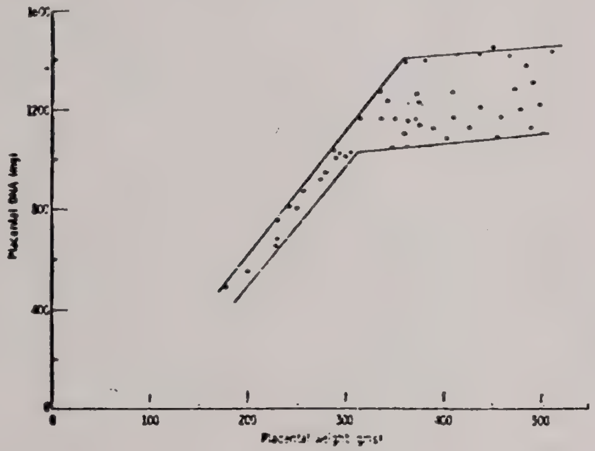
offspring of rats semi-starved during gestation and lactation by limiting the food and protein of their mother in pregnancy or by weaning large numbers of young with one mother are permanently growth-stunted and show metabolic defects. They also have a decreased efficiency for food utilization with a significant wastage of amino acids via the urinary tract.

Winick and Noble[4] have further shown that the rat's placenta growth pattern is similar to that of other organs; no further deoxyribonucleic acid is formed by the placenta after the seventeenth day of gestation. Thereafter, additional growth in size of the placenta is accompanied by increase in ribonucleic acid or of ribonucleic acid and cell protein. They[5] have also demonstrated comparable results from the analysis of fifty normal human placentae from various gestation periods. The placental weight, protein (Figure 2) and ribonucleic acid (Figure 3) continued to increase linearly until term. However, the rate of increase in placental deoxyribonucleic acid (Figure 4) rapidly declined when the placenta weighed approximately 300 gm. or the fetus 2300 gm. Thus, cell division of the human placenta stops at approximately the eighth month of gestation.

The Human Brain

In the human, deoxyribonucleic acid increases in the brain cells until approximately six



Placental DNA versus placental weight.

Figure 4*

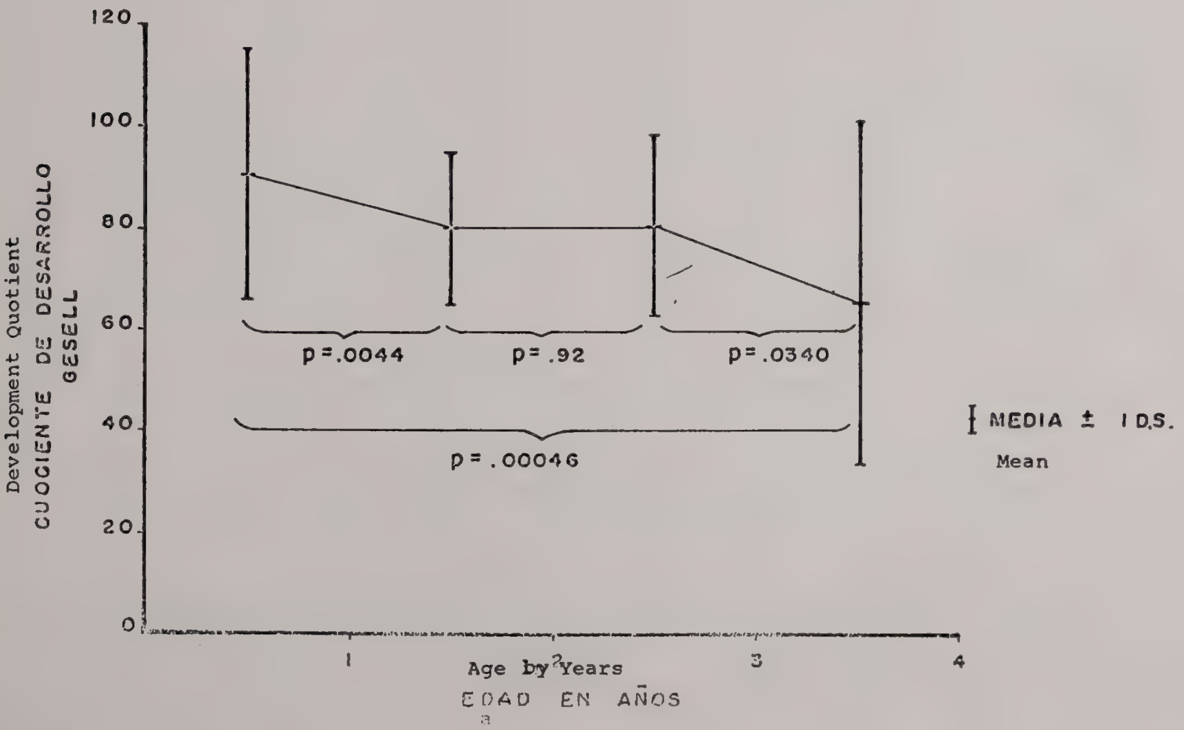


Figure 5

*Myron Winick, Anthony Coscia, and Adele Noble: Cellular Growth in Human Placenta. Pediatrics, Vol. 39, February 1967.

months of age. Organ weight, ribonucleic acid, and cell protein continue to increase in a linear fashion for over twelve months. By analysis of a limited number of human infants' organs, Winick[6] has shown that calorie and protein malnutrition in the first three to six months of life results in a reduction of deoxyribonucleic acid. Ribonucleic acid and protein per cell were normal. The deoxyribonucleic acid reduction correlated closely with the reduction in body weight when the infant had been malnourished since birth.

Vitale's[7] studies in Colombia show a progressive decrease in intellectual ability (as measured by the Gesell method) of infants malnourished during early infancy (Figure 5).

Thus it has been shown that deoxyribonucleic acid synthesis to make all of the cells of the mature brain, whether in rats, pigs, or humans, requires a certain minimum of calorie and protein availability during pregnancy and early infancy.

Conclusions

From these preliminary data, intensive effort is required to assure an adequate supply of calories and protein for the neonate and infant. Where a country's total food resources are inadequate for the entire population, upgrading of the society demands that preferential nutritional sustenance be allocated to the infants. I am aware that concomitant re-education of the mothers may be needed to make the implementation feasible. But the rewards for an underdeveloped country's meeting this challenge would be predictably evident in *one* future generation.

History of Medicine

Development of Controlled Cardiac Pacemaking

ONE OF THE FIRST recorded cases of the use of electricity occurred in the year 15 A.D. when a freed slave of Tiberius Caesar, suffering from gout, stepped on a flat medium-sized fish, received a severe shock and, the story goes, was cured.*

Controlled electrical stimulation of the myocardium has become a reality during the last two decades, the major breakthroughs being the development of the concept of direct myocardial stimulation by an attached electrode, the transistor and solid-state electronics. Prior to this, experiments involving stimulation of the heart, nerves and muscles were carried out over a 200-year span following initial experiments by Luigi Galvani.[1]

Electrical Shock

The experimental and therapeutic use of electrical shock on living tissue was published by Giovanni (John) Aldini, the nephew of Galvani, in 1819.[2] He described his studies done on fresh cadavers and mentioned two cases contained in the register of the Royal Humane Society of Great Britain (for the years 1774 and 1787) where electrical shocks had seemingly restored life. The first of these described "a child, three years old, who fell from a one pair of stairs' window upon the pavement and was taken up without signs of life. A medical practitioner being sent for declared that nothing could be done, and that the child was irrevocably dead; but a gentleman having proposed a trial of electricity, the parents consented. At least 20 minutes elapsed before he could apply the shock, which he gave to various parts of the body without any appearance of success. On directing a few shocks to the chest, a small pulsation became perceptible, and soon after the child began to sigh and to breathe, though with great difficulty; in about 10 minutes, it vomited. A kind of stupor remained for some days; but the child was restored to perfect health and spirits in about a week."[2]

The second case involved "a lad in perfect health, who fell from a stairs' window into an area and was taken up to all appearance dead. Upon the strictest examination, no mark of violence could be discovered either upon the head or any other part. After a variety of means had been tried by a surgeon without effect, the lad was pronounced dead and sent home. A gentleman (past whose house he was carried), happening to inquire into the circumstances of the case, wished to try the effect of electricity. After four small shocks had been given, the lad showed some signs of life; and with further shocks, he gradually recovered, so that in less than two hours, he was able to walk about the house."[2]

The electrical current in Aldini's experiments was generated from a crude battery consisting of zinc plates coated with copper and placed in an acid solution. Current was then conducted through two "leads" to the subject, the areas of electrode attachment having been moistened with salt water.

---

*Hammond, B. J.: A History of Electric Therapy. Part I. World Med Elect Instru 3:44, 1965.

For the next 100 years, cardiac stimulation by electrical currents was carried out via the nervous system rather than by direct myocardial excitation. In 1867 Walshe[3] stated that "Valentine, Henle, Budge and others have distinctly shown that the heart's action may be re-excited, after stoppage by galvanic stimulation of the roots of the spinal accessory nerve, of the first four cervical nerves, and of the sympathetic filaments belonging to the organ." In 1883, Professor William Erb at the University of Leipzig,[4] stimulated the vagus nerve in the neck to treat cardiac arrhythmias with "good results."

Other physicians during this period advocated electrical shock as a treatment for all human ailments. A book that effected this thinking was a "Handbook for General Practioners" written by Dr. E. H. Monell[5] (1897), which described the use of electric currents in such diverse conditions as mental derangements, leiomyomata uteri, and spinal meningitis occurring after a fall.

INVENTORS
Albert S. Hyman & Charles Henry Hyman

Figure: Photograph of a patent for an "Artificial Pace Maker for the Heart" filed by Albert and Charles Hyman* on March 12, 1930, and granted on June 13, 1933. This unit (weighing 7.2 kg.) produced cardiac contractions by sending an electrical impulse through a needle (bipolar in type) placed percutaneously into the myocardium. The thinking of these investigators (far in advance of their time) lay dormant for almost twenty years until the development of solid-state electronics made clinical use of such devices possible.[12]

---

*Head, Mechanical Laboratory, Witkin Foundation.

The Needle Electrode

In 1932 Hyman,[6] while investigating the ability of a needle prick to stimulate and revive a heart in asystole, artificially produced systolic contractions by means of an electrical current flowing through a needle electrode placed percutaneously directly into the myocardium. His apparatus (weighing 7.2 kg.) consisted of a magneto generator which created the stimulating current. This could be rewound by a spring motor without affecting the output from the generator. Current then passed down the percutaneously inserted needle (bipolar in type) to the tip where it came in contact with the myocardium (Figure). He made mention of the successful resuscitation of an infant, reported by Gould at the Medical Congress in Sydney, Australia, in 1929,[6] by means of electrical stimulation of the heart through a percutaneous needle electrode and suggested the more frequent clinical use of this artificial electrical pacemaking technique.

While Marmorstein[7] first described electrical endocardial stimulation of the dog heart in 1927 by means of an intravenous electrode, this approach was not used again until 1951 when Callaghan and Bigelow[8] experimented successfully with direct external and intravenous endocardial stimulation of the sino-atrial node and right atrium by means of unipolar and bipolar electrodes in hypothermic and normothermic dogs. Finally, Furman[9] in 1959 made clinical use of this technique, describing right ventricular endocardial stimulation of the heart in complete heart block by means of an intravenous electrode. In 1952 Zoll[10] made use of prolonged rhythmic electrical stimulation of the heart through the intact chest wall in two patients in complete block who had developed prolonged periods of ventricular asystole. One patient survived.

Open heart surgery in its initial stages and the occurrence of complete atrioventricular block following repair of certain intracardiac defects spurred Lillehei and associates, Weirich[11] and Thevenet,[12] in 1958 to demonstrate for the first time that the cardiac rate could be more effectively controlled by electrically stimulating the heart directly from an external power source through a stainless steel wire inserted into the myocardium.

The first successful treatment of complete heart block in man by means of an electrical pacemaker connected to a myocardial electrode took place January 30, 1957, at the University of Minnesota Hospitals.[11] All of these units were primarily unipolar in design, i.e., one stimulating electrode in the myocardium with a second indifferent electrode plate placed subcutaneously. While bipolar electrodes had previously been used, Hunter and Roth[13] in 1959 advocated the use of and designed a bipolar electrode for clinical use, that could be directly inserted into the myocardium.

The Pacemaker

A power source external to the patient was used in all these developments until 1960 when further miniaturization allowed the entire pacemaker (electrodes plus power source) to be totally implanted at operation in a patient. These clinical devices were reported separately by Zoll,[14] Kantrowitz[15] and Chardack.[16]

Although Faraday had described electromagnetic induction in 1831, experiments with living tissue utilizing this method were not carried out for almost 100 years. In 1933 and 1934 Loucke,[17] Light and Chaffee[18] and Fender [19] stimulated nerve tissue by means of buried collodion-coated coils through inductive coupling to a primary coil, while Abrams[20,21] first stimulated the myocardium in 1960 utilizing a similar arrangement.

Newman[22] in 1937, Greig[23] in 1944, Mauro[24] in 1948, Davey[25] in 1949 and Mauro[26] in 1950 all reported on the stimulation of nerve tissue by creating an impulse in a secondarily implanted coil using radio frequency transmission. These experiments culminated in the clinical use of this technique for myocardial stimulation by Glenn[27] (1959) and Widmann[28] (1964). Both inductive coupling and radio frequency transmission, however, necessitated a power source external to the patient. Although this method has been used successfully in patient care, most investigators have continued to utilize units in which the electrodes plus power source could be totally implanted.[29-42]

Although complete heart block, up until quite recently, was considered to be a rather rare clinical condition, we now know quite differently for more than 25,000 patients have been fitted with pacemakers connected to myocardial electrodes since these devices came into clinical use only a few years ago.

A Weeping and a Wailing and a Nationalization of Teeth

Oh, to be in England
Now that Health is free!
Not a farthing needed
For an appendectomy.
Dentures for the asking,
For husband, child, or spouse;
Oh, to be in England
Now that Health is "on the house."
—Dr. Francis Leo Golden: Jest What the Doctor Ordered.

MINNESOTA STATE MEDICAL ASSOCIATION
116TH ANNUAL MEETING MAY 26•27•28, 1969
CONVENTION HALL, MINNEAPOLIS AUDITORIUM
"THE UPPER-MIDWEST'S GREAT MEDICAL MEETING"

Drastic innovation can best describe the scientific program for the 116th Annual Meeting of the Minnesota State Medical Association May 26, 27 and 28, Convention Hall, Minneapolis Auditorium.

Three exciting days . . . filled with a variety of business, scientific and social events have been arranged by the Committee on Scientific Assembly. President, Doctor O. L. N. Nelson, Minneapolis, is General Chairman of the Committee. Hosts for the 116th Annual Meeting are the members of the Hennepin County Medical Society. Doctor R. E. Anonsen, Minneapolis, President of the Hennepin County Medical Society, is also Chairman of the Committee on Local Arrangements.

A New Approach

Workshop Session '69 is the most recent step taken by the Committee to streamline the scientific program. Featured will be a series of thirty-two workshops, each one hour in length. Each workshop will be given twice, giving physicians the opportunity to attend a maximum number of presentations. Speakers for the workshop sessions have been selected from the ranks of eminent Minnesota specialists and consultants, who will discuss every-day problems encountered by the practicing physician. Each workshop session is limited to 20 physicians, and therefore pre-registration is encouraged by the Committee.

The Workshop '69 schedule is as follows:

MONDAY, MAY 26
IDENTICAL WORKSHOP SESSIONS
2:00-3:00 P.M. & 3:45-4:45 P.M.

What To Do Until The Psychiatrist Comes	T. P. Burton
Anesthesia and Pulmonary Disease	H. D. Westgate
Drugs For Nervousness?	B. C. Schiele
Preventing Complications of Acute Meningitis	M. R. Gomez
Current Status Of Organ Transplantation	J. S. Najarian
Hemorrhoids—To Operate Or Not To Operate That May Be The Question	C. E. Culp
Cutaneous Patterns Of Fatal Disease	R. K. Winkelmann
Hand Injuries—13 Things To Avoid	K. H. Sponsel
Thyroid Function Testing—An Exercise In Medical Detection	C. A. Gorman
Burns—How To Treat Them	J. W. LaFave
Multiple Injuries	J. F. Perry, Jr. Donald L. Erickson, Paul Arnesen, Josiah Fuller, Harrison Farley

TUESDAY, MAY 27
IDENTICAL WORKSHOP SESSIONS
2:00-3:00 P.M. & 3:45-4:45 P.M.

Children Who Don't Grow	A. B. Hayles
Anesthesia And Patient Monitoring	J. J. Buckley
Thyroid Disease—A Therapeutic Controversy	A. L. Schultz F. C. Goetz F. R. Keating O. H. Beahrs A. J. Kremen

Clotters And Bleeders	J. R. Edson
Belchers And Bloaters	W. L. Blackwood, M. D. Levitt
Chest Injuries	R. E. Larson, J. A. Culligan Josiah Fuller
Reflux And The Assaulted Kidney	G. W. Koos
Menopause—An Organic vs. A Psychiatric Problem?	B. F. P. Williams
Rheumatism And Drugs	P. H. Andreini
The Threatening Eye	W. J. Slack
CCU ECG Group Problem Solving Sessions	Gerald B. Lee, John W. LaBree

WEDNESDAY, MAY 28
IDENTICAL WORKSHOP SESSIONS
9:30-10:30 A.M. & 11:00-12:00 Noon

Prevention Of Rh Disease	H. F. Polesky, E. B. Berglund, A. R. Thelemann
Anesthesia In The Office And Emergency Room	J. W. Smith
Computer Applications In Medical Practice	J. A. Hilger
Fertility And Infertility	John Sciarra
Abdominal Pain	L. J. Hay
Practical Management Of Acute Head Injuries	R. F. Galbraith, E. S. Wisiol
Nonsuture Technique In Surgical Treatment Of Varicose Veins	D. A. Felder
The New Diuretics	D. A. Duncan, Ross M. Tucker
Pulmonary Insufficiency	W. A. Corson, R. V. Ebert
Saving The Cold and Pulseless Limb	Yoshio Sako, C. W. Manz

"In Depth" Treatment

The success of the "in depth" sessions initiated at the 1968 meeting has given impetus to a similar series at the 1969 meeting. The first of two "in depth" sessions will be held Monday, May 26, 9:30 A.M. to 12:00 P.M. Doctor William E. Segar will be in charge of the session titled "Fluids and Electrolytes—How Much, What Kind and When." "Cancer Chemotherapy" will be treated "in depth" Tuesday, May 27, at 9:30 A.M. Chairman for this session is Doctor David Ahmann. Topics and participants in the Chemotherapy session are:

The Chemotherapy Of Solid Tumors In Children	Loren N. Vorlicky
The Chemotherapy Of Gastrointestinal Cancer	Irving J. Lerner
Progress In The Management Of The Patient With Lymphoma	John H. Brown
Current Thoughts About The Chemotherapy Of Leukemia	Joseph M. Kiely
Testicular Cancer—Current Chemotherapy	John F. Foley Omaha, Neb.
The Medical Management Of Disseminated Breast Cancer	David L. Ahmann

The program is acceptable for 14 prescribed hours by the American Academy of General Practice.

Noon Luncheons Feature Popular Topics

Two luncheon meetings scheduled for Monday and Tuesday mark another departure from the traditional round table luncheons of past years.

On Monday, May 26, 12:15 P.M., Doctor Arthur C. Aufderheide, Duluth, will speak on the topic "To the North Pole by Snowmobile." The Tuesday luncheon speaker will be the Reverend Philip Hansen, White Bear Lake. Reverend Hansen is Chairman of the Minnesota Commission on Alcohol Problems, and will speak on the topic of "Alcoholism."

Business Sessions

The House of Delegates meeting and Reference Committee meetings will highlight the business session of the 116th Annual Meeting. The House will convene Sunday, May 25, 2:00 P.M., Holiday Inn Central, and will reconvene

Tuesday, May 27, 7:00 P.M. Reference Committees will meet Sunday at 8:00 P.M. The Annual Banquet will be held Monday, May 26, 7:00 P.M. This marks another change from the traditional Tuesday date. The banquet will be preceded by a social hour beginning at 6:00 P.M. Dancing and a late evening buffet will climax the banquet program. Fifty Club candidates will be honored guests at the banquet.

The Distinguished Service Medal will be awarded and a medal for the outstanding scientific exhibit will be presented by the Southern Minnesota Medical Association.

The Delegates, New Members, Officers and Sportsmen's dinner will be held Sunday, May 25, 6:00 P.M. at the Holiday Inn Central.

Sports Events

The annual golf tournament will be held at the Midland Hills Country Club, St. Paul. Tee off time is 9:00 A.M., Sunday, May 25. Early tee times are recommended. Prizes will be awarded. The green fee is $15.00. Skeet and trap events, including razzle dazzle, are scheduled Sunday, May 25, from 10:00 A.M. to 4:00 P.M. at the Minneapolis Gun Club. Prizes will be awarded. Participants in sports events and their wives are invited to attend as guests of the Minnesota State Medical Association, the Delegates, New Members, Officers and Sportsmen's dinner on Sunday. An annual bridge tournament is also scheduled for Sunday night at 8:00 P.M.

Pre-registration Desirable

Physicians are encouraged to pre-register by completing the registration card enclosed with current issues of the Newspage and the official Annual Meeting program mailed to all members. By completing and returning this card by May 5 to the State Office physicians can be certain that their badges will be waiting for them at the advance registration desk in the Minneapolis Auditorium Convention Hall.

Time Table

MONDAY, MAY 26

A.M.	Visit scientific and technical exhibits
9:30 A.M. to 12:00 P.M.	"FLUIDS AND ELECTROLYTES—HOW MUCH, WHAT KIND AND WHEN" William E. Segar
(Intermission: 10:30 A.M.-11:00 A.M. Visit scientific and technical exhibits)	
12:15 P.M.	LUNCHEON—"TO THE NORTH POLE BY SNOWMOBILE" Arthur C. Aufderheide
1:30 P.M.	Visit scientific and technical exhibits
2:00 P.M. to 3:00 P.M. Repeated: 3:45 P.M. to 4:45 P.M.	WORKSHOPS
7:00 P.M.	ANNUAL BANQUET Reception at 6:00 P.M. Presentations and Entertainment Dancing and Late Evening Buffet

TUESDAY, MAY 27

A.M. Visit scientific and technical exhibits
9:30 A.M. to 12:00 P.M. "CANCER CHEMOTHERAPY"
Chairman—David L. Ahmann

THE CHEMOTHERAPY OF SOLID TUMORS IN CHILDREN
Loren N. Vorlicky

THE CHEMOTHERAPY OF GASTROINTESTINAL CANCER
Irving J. Lerner

PROGRESS IN THE MANAGEMENT OF THE PATIENT WITH LYMPHOMA
John H. Brown

CURRENT THOUGHTS ABOUT THE CHEMOTHERAPY OF LEUKEMIA
Joseph M. Kiely

(Intermission: 10:30 A.M.-11:00 A.M.
Visit scientific and technical exhibits)

TESTICULAR CANCER—CURRENT CHEMOTHERAPY
John F. Foley

THE MEDICAL MANAGEMENT OF DISSEMINATED BREAST CANCER
David L. Ahmann

Questions and discussion by the participants

12:15 P.M. LUNCHEON—"ALCOHOLISM"
Reverend Philip Hansen, White Bear Lake
1:30 P.M. Visit scientific and technical exhibits
2:00 P.M. to 3:00 P.M. WORKSHOPS
Repeated: 3.45 P.M. to 4.45 P.M.

WEDNESDAY, MAY 28

A.M. Visit scientific and technical exhibits
9:30 A.M. to 10:30 A.M. WORKSHOPS

(Intermission: 10:30 A.M.-11:00 A.M.
Visit scientific and technical exhibits)

Repeated: 11:00 A.M. to 12:00 P.M.

EXHIBITS

Because most of the Annual Meeting activities will be held in the Minneapolis Auditorium Convention Hall, physicians will have more time to visit the many excellent scientific and technical booths. All physicians attending the meeting are invited to visit the technical exhibits and extend their appreciation to the representatives of the firms who have participated in this meeting, thus insuring future meetings for our Association.

The Woman's Auxiliary will meet in conjunction with the Annual Meeting of the Minnesota State Medical Association.

Meetings and Announcements

We live and learn, but not the wiser grow.—John Pomfret

MAY

Minnesota State Medical Association
116th Annual Meeting, Convention Hall, Minneapolis, May 26, 27, 28.

Mankato Golf Club, 7 P.M., May 26.

Range Medical Society
Executive & General Meeting, 7:15 P.M., Dinner—Location to be announced, May 27.

Minnesota Academy of Ophthalmology & Otolaryngology
Regular meeting to coincide with time and place of Minnesota State Medical Association annual meeting.

Courses at the University of Minnesota

New Knowledge in the Diagnosis and Treatment of Rheumatic Diseases

This course is planned for May 9 and 10, and is directed toward the practicing physicians with emphasis on this newer information and its application to the rheumatic problems encountered in every medical practice. Ample time has been left for discussion after each presentation so participants will have the chance to have their questions answered.

The course has been planned by Doctors John G. Mayne and John W. Worthington, Mayo Graduate School of Medicine, and is co-sponsored by the Committee on Rheumatology and Rheumatic Diseases of the Minnesota State Medical Association, and by the Minnesota Chapter of the Arthritis Foundation. The course is offered by the Office of Postgraduate Educational Activities of the College of Medical Sciences, and conducted by the Department of Conferences and Institutes, General Extension Division, University of Minnesota. Tuition is $25.00. Approved A.A.G.P. hours: 11 hours.

Gastro-Intestinal Surgery

The University of Minnesota will present a course on Gastro-Intestinal Surgery on May 21-24, 1969.

Anesthesiology

The University of Minnesota will present a Continuation Course in Anesthesiology May 5-7, 1969. The theme of this year's course is *Do the Patient No Harm.*

For further information concerning all of the above courses contact: Lee D. Stauffer, College of Medical Sciences, Box 193 Mayo Building, University of Minnesota, Minneapolis 55455.

Hot under the collar...
high under the cuff.

Sometimes
he forgets he has hypertension, gets hot under the collar. . . high under the cuff.

For such patients, consider **Regroton®**

chlorthalidone 50 mg.
reserpine U.S.P. 0.25 mg.

To lower blood pressure
and allay anxiety in hypertension.

For brief summary of prescribing information, see next page.

RE-6392

Regroton® Geigy

chlorthalidone 50 mg.
reserpine U.S.P. 0.25 mg.

the once-a-day tablet for anxious hypertensives

Regroton is a combination of two basic antihypertensives designed to lower blood pressure and allay anxiety in hypertension. With Regroton he can keep his shirt on and you can keep his blood pressure down.

Before prescribing, please review carefully the indications, contraindications, warning, precautions, adverse reactions and dosage information below.

Regroton®
Each tablet contains:
chlorthalidone 50 mg.
reserpine U.S.P. 0.25 mg.

Indications: Hypertension.
Contraindications: History of mental depression, hypersensitivity, and most cases of severe renal or hepatic diseases.
Warning: With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has frequently been required and deaths have occurred. Discontinue coated potassium-containing formulations immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur. Discontinue one week before electroshock therapy, and if depression or peptic ulcer occurs.
Use in pregnancy: Because chlorthalidone may cross the placental barrier and appear in cord blood and thiazides may appear in breast milk, this drug should be used with care in pregnant patients and nursing mothers. When used in women of childbearing age, the potential benefits of the drug should be weighed against the possible hazards to the fetus. Use of chlorthalidone may result in fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. Increased respiratory secretions, nasal congestion, cyanosis and anorexia may occur in infants born to reserpine-treated mothers.
Precautions: Antihypertensive therapy with this drug should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents, other potent antihypertensive drugs, or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. To avoid hypotension during surgery, discontinue therapy with this agent two weeks prior to elective surgical procedures. In emergency surgery, use, if needed, anticholinergic or adrenergic drugs or other supportive measures as indicated. Because of the possibility of progression of renal damage, periodic kidney function tests are indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated. Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, the drug should be discontinued and potassium supplements given, provided the patient does not have marked oliguria.
Take particular care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Severe salt restriction is not recommended. Use cautiously in patients with ulcerative colitis or gallstones (biliary colic may be precipitated). Bronchial asthma may occur in susceptible patients.
Adverse Reactions: The drug is generally well tolerated. The most frequent side effects are nausea, gastric irritation, vomiting, diarrhea, constipation, muscle cramps, headache, dizziness and acute gout. Other potential side effects include angina pectoris, anxiety, depression, bradycardia and ectopic cardiac rhythms (especially when used with digitalis), drowsiness, dull sensorium, hyperglycemia and glycosuria, hyperuricemia, lassitude, restlessness, transient myopia, impotence or dysuria, orthostatic hypotension which may be potentiated when chlorthalidone is combined with alcohol, barbiturates or narcotics, leukopenia, aplastic anemia, skin rashes, thrombocytopenia, agranulocytosis, nasal stuffiness, increased gastric secretions, nightmare, purpura, urticaria, ecchymosis, weakness, uveitis, optic atrophy and glaucoma, and pruritus. Eruptions and/or flushing of the skin, a reversible paralysis agitans-like syndrome, blurred vision, conjunctival injection, increased susceptibility to colds, dyspnea, weight gain, decreased libido, dryness of the mouth, deafness, anorexia, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Jaundice, xanthopsia, paresthesia, photosensitization and necrotizing angiitis are possible.
Average Dosage: One tablet daily with breakfast.
Availability: Pink, single-scored tablets in bottles of 100 and 1000.

118th Annual Convention
AMA
NEW YORK CITY
JULY 13-17, 1969

The magnetism and the grandeur that characterizes New York City will provide a superb setting for AMA's 118th Annual Convention in July. Plan to attend now and look forward to five memorable and stimulating convention days in a city of unlimited excitement.

Continue your postgraduate education with a varied program of • four General Scientific Meetings on Chronic Pulmonary Insufficiency and Problems of Air Pollution, Human Sexuality, Impact of Medical Education on Patient Care, and Physical Fitness and Aging • 23 Section Programs • Color Television • Medical Motion Pictures • and over 700 scientific and industrial exhibits. The nation's outstanding medical authorities will lecture and discuss the significant advances in today's medicine.

In addition the AMA TV network will present more than 40 hours of convention programming.

Reserve now for the Scientific Awards Dinner in honor of the Scientific Award Winners—Wednesday, July 16, 1969. Since space is limited, we suggest you make your reservations before June 30, 1969. Tickets are $10.00 each, payable in advance.

The complete scientific program, plus forms for advance registration and hotel accommodations, will be featured in JAMA, May 26, 1969.

NEW YORK CITY, NEW YORK • JULY 13-17, 1969

Located in Michigan's serene, scenic recreation area on Grand Traverse Bay. Contact Dr. Paul E. Kauffman, Director of Training, Traverse City State Hospital, Traverse City, Michigan 49684. An equal opportunity employer.

Science

A contemporary historian, speaking of our scientific advances, expresses the choice before us: "If things go well, the epitaph of history may run: 'Here lie the technicians, who united mankind.' And if things go badly: 'Here lie the technicians, who exterminated the human race.' "—Christian Century

Minnesota Medicine at a Glance

Post-Intubation Granuloma of Larynx—*Schlorf and Duvall* Page 717

The large number of operations currently being performed via endotracheal anesthesia demands that all concerned be aware of the complication of post-intubation granuloma of the larynx. It should be suspected, and treated, whenever a patient becomes hoarse or develops ear pain or a persistent cough, several weeks after a translaryngeal intubation. The lesion is pathologically a pyogenic granuloma, results from trauma to the larynx and has a characteristic laryngoscopic appearance. It often responds to a medical regimen, but in problem cases surgical removal is indicated.

Hepatitis in Infectious Mononucleosis—*Kitzmiller* Page 721

Eighteen cases of syncope on coughing have been diagnosed at the Mayo Clinic in the last eighteen years. The typical patient is a heavy user of alcohol and a heavy smoker, and is obese, with clinical or laboratory evidence of obstructive lung disease. Therapy primarily is correction of bad habits.

Vaginal Hormonal Cytology—*Litwak and Mussey* Page 731

The value of exfoliative cytology of vaginal cells in interpreting the constant interplay of hormones should come under close scrutiny. Physicians concerned with vaginal cytology should find this article helpful in defining basic indices. The normal vaginal smear is described as well as smears associated with the period before and after ovulation. Several clinical syndromes with a characteristic vaginal cytology are described: among them, ovarian decline, estrogen therapy, and threatened abortion. The use of hormonal cytologic studies in children is briefly described. The hormonal colpocytologic procedure appears to add a significant increment to the physician's judgment.

Toxoplasmosis and Pneumocystis Carinii Pneumonitis—*Theologides et al.* Page 737

A case of seminoma of the left testis, treated with radiation therapy and followed by chronic lymphatic leukemia, is described in detail. The patient was treated with radiation and androgen steroids. He died of a combined infection with pneumocystis carinii and toxoplasmosis. The authors urge early diagnosis, since therapy may be life-saving.

Treatment of Myocardial Infarction—*Trajano et al.* Page 743

The coronary care unit at Mount Sinai Hospital in Minneapolis reports on 100 acute myocardial infarctions with a hospital mortality of 21 percent. The authors estimate the treatment in the Coronary Care Unit reduced the mortality 11 to 13 percent. The reduction was effected by more favorable results in arrhythmias.

Drug Fever Due to Procainamide—*Pierach* Page 813

A 64-year-old male patient demonstrated drug fever due to procainamide. Fever started sixteen days after commencement of Pronestyl® therapy, 250 mg., four times daily, by mouth. The day after discontinuance the temperature dropped to normal, but later rose briefly again after a single provocative dose of 250 mg.

"Eastern Shore" Robert L. Feldmann, M.D.

JUNE, 1969

For the "Cheater Eater"

Formulas: Each 'Dexamyl' *Spansule* capsule No. 1 contains 10 mg. of Dexedrine® (brand of dextroamphetamine sulfate) and 1 gr. of amobarbital, derivative of barbituric acid (Warning, may be habit forming). Each 'Dexamyl' *Spansule* capsule No. 2 contains 15 mg. of Dexedrine (brand of dextroamphetamine sulfate) and 1½ gr. of amobarbital (Warning, may be habit forming).
Before prescribing, see complete prescribing information in SK&F literature or *PDR*.
Contraindications: Hyperexcitability, undue restlessness, hyperthyroidism, porphyria; in patients on MAO inhibitors.
Precautions: Use with caution in patients hypersensitive to sympathomimetics or barbiturates and in coronary or cardiovascular disease or severe hypertension. Excessive use of the amphetamines by unstable individuals may result in a psychological dependence. Rarely, symptoms of toxic psychosis (hallucinations, confusion, panic states, etc.) may occur with amphetamines, usually after prolonged high dosage. In these instances, withdraw the medication. Use cautiously in pregnant patients, especially in the first trimester.
Adverse Reactions: Overstimulation, restlessness, insomnia, g.i. disturbances, diarrhea, palpitation, tachycardia, elevated blood pressure, tremor, sweating, impotence and headache.
Supplied: In bottles of 50.

Dexamyl®

brand of dextroamphetamine sulfate and amobarbital

Spansule®

brand of sustained release capsules

curbs appetite
encourages normal activity
dispels diet discouragement

SK&F
Smith Kline & French Laboratories

LACTINEX®

TABLETS & GRANULES

- **to help restore and stabilize the intestinal flora**
- **for fever blisters and canker sores of herpetic origin**

Lactinex contains both *Lactobacillus acidophilus* and *L. bulgaricus* in a standardized viable culture, with the naturally occurring metabolic products produced by these organisms.

Lactinex has been shown to be useful in the treatment of gastrointestinal disturbances, and for relieving the painful oral lesions of fever blisters and canker sores of herpetic origin.[1,2,3,4,5,6,7,8]

No untoward side effects have been reported to date.

Literature on indications and dosage available on request.

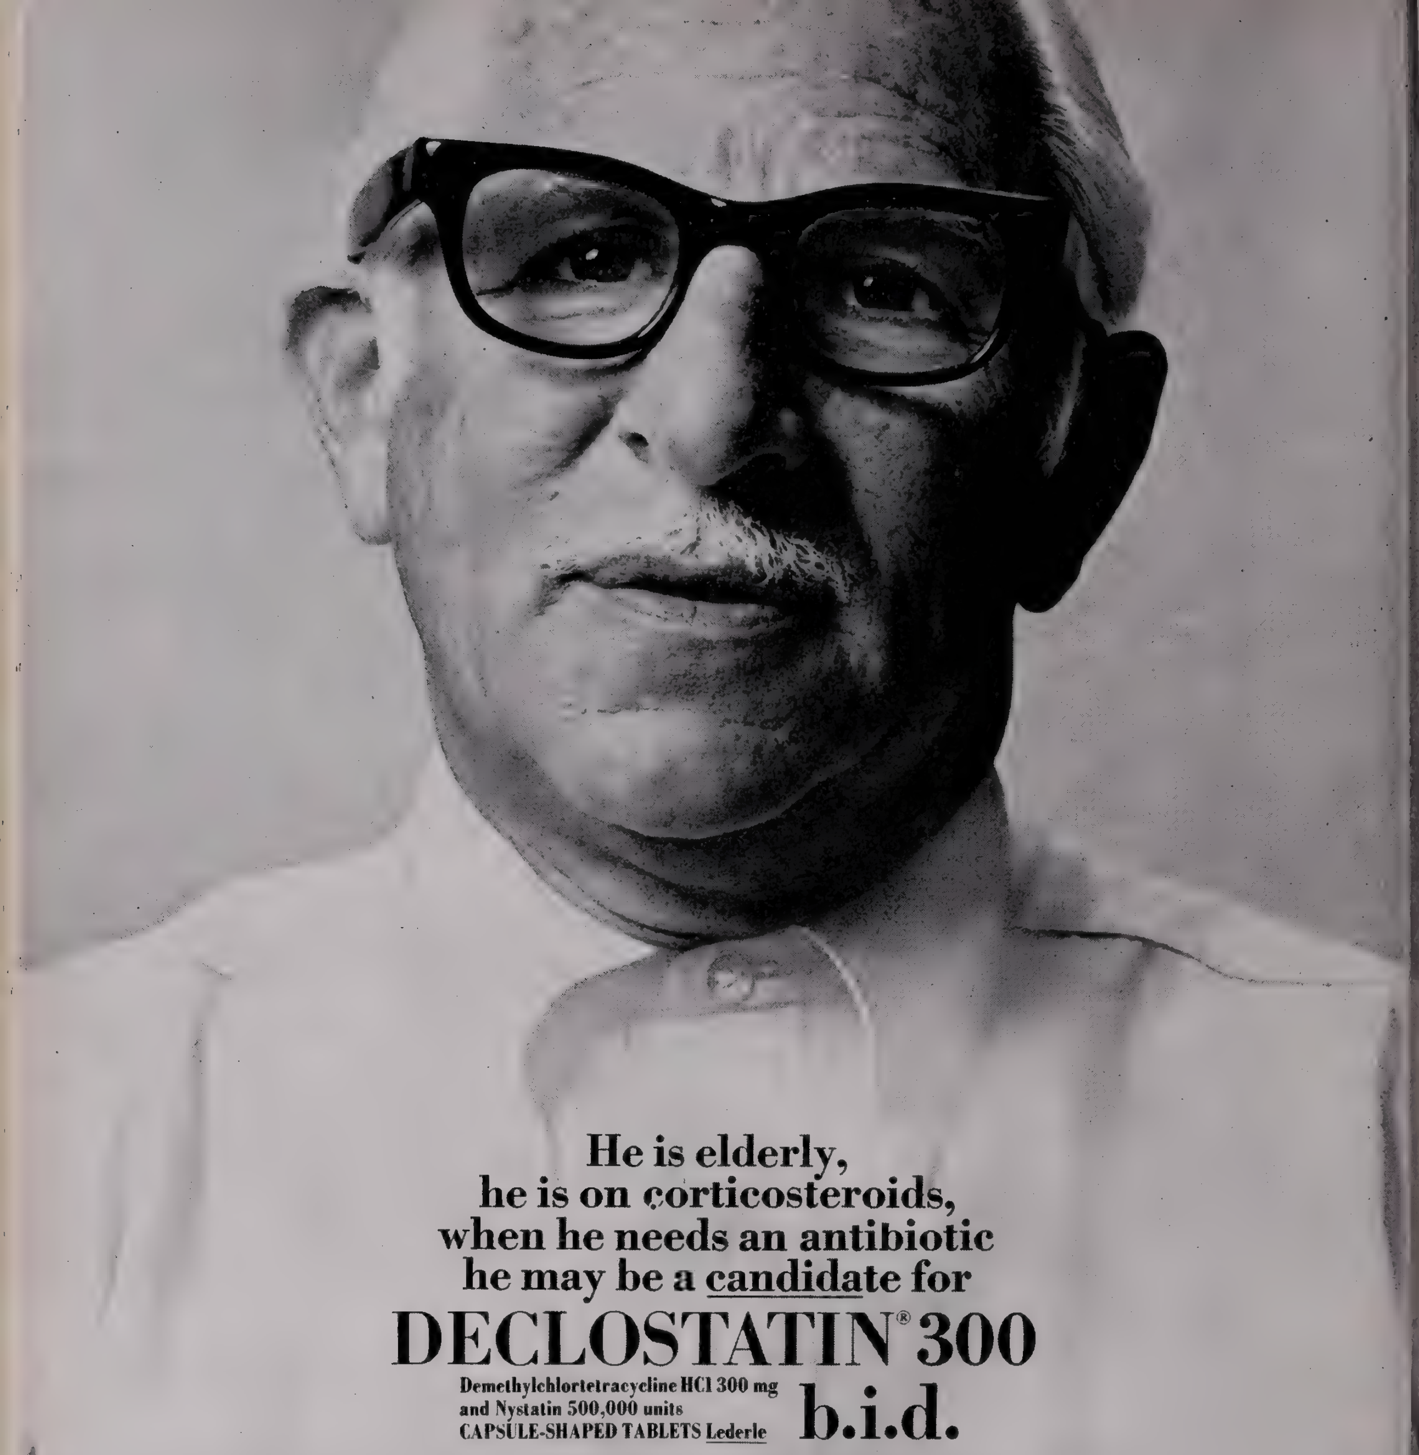
LIBRARY OF THE
COLLEGE OF PHYSICIANS
OF PHILADELPHIA
JUN 24 1969



He is elderly, he is on corticosteroids, when he needs an antibiotic he may be a candidate for

DECLOSTATIN® 300

Demethylchlortetracycline HCl 300 mg
and Nystatin 500,000 units
CAPSULE-SHAPED TABLETS Lederle

b.i.d.

To guard susceptible patients against intestinal monilial overgrowth during broad-spectrum therapy—the protection of nystatin is combined with demethylchlortetracycline in DECLOSTATIN.

For your susceptible candidates, prescribe DECLOSTATIN -the broad-spectrum therapy that prevents monilial overgrowth.

Contraindication: History of hypersensitivity to demethylchlortetracy-line or nystatin.

Warning: In renal impairment, usual doses may lead to excessive accumu- ation and liver toxicity. Under such conditions, lower than usual doses re indicated, and, if therapy is prolonged, serum level determinations nay be advisable. A photodynamic reaction to natural or artificial sun- ight has been observed. Small amounts of drug and short exposure may roduce an exaggerated sunburn reaction which may range from ery- hema to severe skin manifestations. In a smaller proportion, photo- llergic reactions have been reported. Patients should avoid direct xposure to sunlight and discontinue drug at the first evidence of skin liscomfort. Necessary subsequent courses of treatment with tetracy- lines should be carefully observed.

recautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriat measures should be taken.

In infants, increased intracranial pressure with bulging fontanels ha been observed. All signs and symptoms have disappeared rapidly upo cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, dia rhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopa ular and erythematous rashes; a rare case of exfoliative dermatitis ha been reported. Photosensitivity; onycholysis and discoloration of th nails (rare). Kidney—rise in BUN, apparently dose related. Transien increase in urinary output, sometimes accompanied by thirst (rare) Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxi Teeth—dental staining (yellow-brown) in children of mothers given th drug during the latter half of pregnancy, and in children given the dru during the neonatal period, infancy and early childhood. Enamel hyp plasia has been seen in a few children. If adverse reaction or idiosy crasy occurs, discontinue medication and institute appropriate therap Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should b given 1 hour before or 2 hours after meals, since absorption is impaire by the concomitant administration of high calcium content drugs, food and some dairy products. Treatment of streptococcal infections shoul continue for 10 days, even though symptoms have subsided.

GENERAL INFORMATION

Authors

Send manuscripts, subscriptions and communications for consideration to minnesota medicine, 375 Jackson Street, St. Paul, Minnesota 55101. Telephone 222-6366.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged.

All manuscripts will be edited and stylized to conform to the format used in minnesota medicine.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

118th Annual Convention
AMA
NEW YORK CITY
JULY 13-17, 1969

The magnetism and the grandeur that characterizes New York City will provide a superb setting for AMA's 118th Annual Convention in July. Plan to attend now and look forward to five memorable and stimulating convention days in a city of unlimited excitement.

Continue your postgraduate education with a varied program of • four General Scientific Meetings on Chronic Pulmonary Insufficiency and Problems of Air Pollution, Human Sexuality, Impact of Medical Education on Patient Care, and Physical Fitness and Aging • 23 Section Programs • Color Television • Medical Motion Pictures • and over 700 scientific and industrial exhibits. The nation's outstanding medical authorities will lecture and discuss the significant advances in today's medicine.

In addition the AMA TV network will present more than 40 hours of convention programming.

Reserve now for the Scientific Awards Dinner in honor of the Scientific Award Winners—Wednesday, July 16, 1969. Since space is limited, we suggest you make your reservations before June 30, 1969. Tickets are $10.00 each, payable in advance.

The complete scientific program, plus forms for advance registration and hotel accommodations, will be featured in JAMA, May 26, 1969.

Equipment and supplies for the medical profession since 1919

President's Letter

As I begin this first letter as your President, I am reminded that we have just observed our 116th Anniversary in May. It was in 1853 that doctors in Minnesota found it necessary and beneficial for the practice of medicine to join together and organize the Minnesota State Medical Association and its component societies. Great credit must be given to all of the members, the various committees and their chairmen, the Council and the officers and all the members of the Houses of Delegates who have worked so diligently and have given so largely of their time to the betterment of our Association over these many years. We must pay homage to them all.

It is disturbing, however, that all doctors in Minnesota have not been members of organized medicine. In 1968 there were 4,989 licensed physicians in Minnesota. Of these, there were 3,375 active members and 423 residency members of the Minnesota State Medical Association and 3,208 active members and 413 residency members of the American Medical Association.

It is human nature, of course, that all people including doctors do not join organizations, or do not agree with policies of organizations. However, it is rather difficult to understand why one who spends so many years in training as does the doctor of medicine is willing to forfeit his right to speak out and be really heard of effectively either by the profession or by the general public.

The doctor who is not a member of his local county or district society, who is not a member of the Minnesota State Medical Association and who is not a member of the American Medical Association has no real voice, though he may be critical of both, in determining the policies of organized medicine or the destiny of the practice of medicine. The Academy of General Practice working together with State Medical Associations and the American Medical Association has brought the General Practitioner back from the brink of no return to a respected and valued position in the Family Practice of Medicine. Likewise, in the years past, the American College of Surgeons pioneered the raising of the standard of surgical practice in hospitals and were able to succeed because of organization.

I therefore ask all members of our Association to make a determined effort to encourage all our brethren to join with us in this great profession we must all strive to improve.

June, 1969

Thioflavine - T

in Basal Cell Carcinoma and Ameloblastoma

WILLARD C. PETERSON, JR., M.D.[*]
ROBERT J. GORLIN, D.D.S.[†]
Minneapolis, Minnesota

In a previous paper, the histologic similarities between basal cell carcinoma and ameloblastoma[‡] were discussed.[1] If one considers the similar origins of skin appendages and the dental apparatus it is not surprising that a histologic similarity may exist between these two tumors.

Between the fifth and seventh week of fetal life both cutaneous and oral ectoderma undergo proliferation; the epidermis becomes double layered, and during the third month *in utero* primary epithelial germs proliferate and reticulum fibers appear in the dermis. Almost analogous changes are taking place orally; at about the sixth intrauterine week, epithelium covering the jaw proliferates at 20 different points corresponding to the future position of the deciduous teeth.

Basal cell carcinoma has been shown to have thioflavine-T reactivity in a certain percentage of specimens studied with this staining method.[2] Because of the histologic similarity between basal cell carcinoma and ameloblastoma, 24 basal cell carcinomas and 12 ameloblastomas were compared on the basis of the thioflavine-T staining technique.

Material and Methods

Sections from 24 formalin-fixed, paraffin-embedded specimens of basal cell carcinoma and 12 specimens of ameloblastoma were stained with hematoxylin and eosin for microscopic comparison. These same tumors were then examined for thioflavine-T reactivity using the method of Hobbs and Morgan.[3] The sections were examined under a microscope (Leitz Ortholux) employing a mercury light source (HBO-200 Osram), using a special cemented barrier filter, UV filter 3mm BG12, and heat absorbing filters (2mm KGI and 4mm BG38). The fluorescence of thioflavine-T was yellowish green. Positive amyloid controls were used with the foregoing technique.

Results

In both series (Table) somewhat over one half of the sections exhibited positive fluorescence with the thioflavine-T method. No definite patterns of fluorescence were observed in either basal cell carcinoma or ameloblastoma. In many of the tumors of both types, fluorescence appeared only in the interstitial areas outlining the individual cells clearly; however, in other sections the fluorescence appeared not only in the interstitial areas but also in many of the tumor cells, giving the appearance of somewhat large homogeneous areas of fluorescence. In basal cell carcinoma, surface keratin as well as keratin within hair follicles fluoresced with this technique. This was, of course, easily identifiable by structure and did not cause confusion.

---

[*] Clinical Assistant Professor, University of Minnesota, Department of Medicine, Department of Dermatology, Minneapolis, Minnesota.

[†] Professor and Chairman, Division of Oral Pathology, School of Dentistry, University of Minnesota, Minneapolis, Minnesota.

[‡] See Test Your Word Score Page 933.

TABLE
Thioflavine—T Reactivity

	Ameloblastoma	Basal Cell Carcinoma
Positive	7	14
Negative	5	10
Total	12	24

Comment

The histologic similarity of basal cell carcinoma and ameloblastoma is considerable (Figures 1 and 2). The question of origin of the basal cell epithelioma is not as yet clearly defined. It occurs almost exclusively on the hair-bearing areas of the body, the face being the most common site of origin. This tumor has been known to metastasize;[4,5] however, this is not a common event. Instead, the tumor tends to invade locally. Histologically, basal cell carcinoma can be divided into differentiated and undifferentiated forms. When differentiation occurs, it is in the direction of hair, sebaceous and apocrine glands. The tumor has a characteristic cell which exhibits a large, oval, deeply basophilic nucleus. The cytoplasm, as a rule, is scanty with an indistinct cytoplasmic membrane.

Ameloblastoma is a tumor of slow growth. It may have its origin in the epithelial lining of a dentigerous cyst, the basal layer of the oral mucous membrane or the epithelial remnants of the enamel organ. Ameloblastoma occurs most frequently in the molar-ramus region of the mandible. It is locally invasive and has a marked tendency to recur following conservative removal. It has also been known to metastasize, but this is a rare event.[6] Microscopically, basophilic epithelial cells are seen grouped in nests and cords within the collagenic fibrous connective tissue stroma. The peripheral cells are cuboidal to columnar in nature; and in the central, loose, stellate reticulum-like area, they exhibit a tendency to differentiation into squamous-like cells (acanthomatous ameloblastoma).

Conclusions

Both basal cell carcinoma and ameloblastoma show certain similarities. In both, the origin is from primordial epithelium; both show a tendency to be locally invasive and to recur if not adequately removed. Both have been reported to metastasize occasionally. Microscopically each is composed of islands of epithelial cells in a similar connective tissue stroma which shows separation or clefting away from the tumor mass. In both, the epithelial cells show polarization away from the border of the tumor. In view of these similarities it is not surprising that ameloblastoma, like basal cell

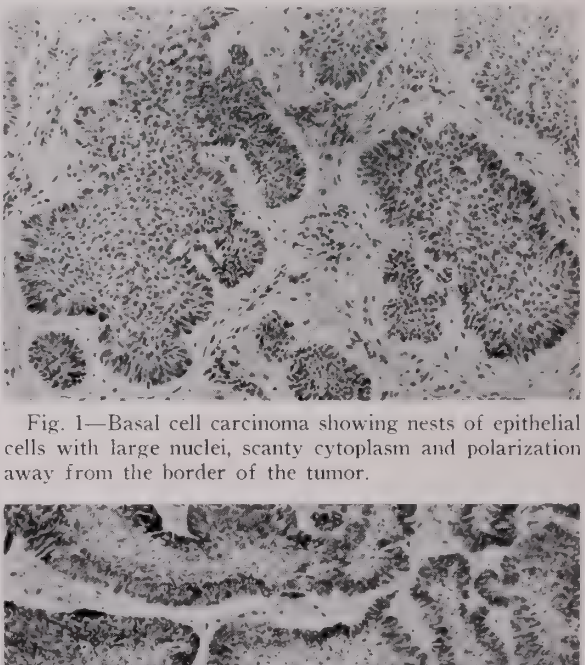

Fig. 1—Basal cell carcinoma showing nests of epithelial cells with large nuclei, scanty cytoplasm and polarization away from the border of the tumor.

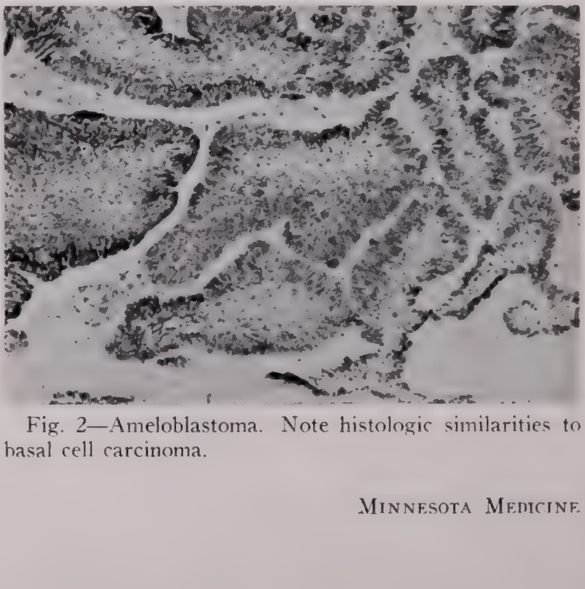

Fig. 2—Ameloblastoma. Note histologic similarities to basal cell carcinoma.

carcinoma, should show considerable thioflavine-T reactivity within the tumor mass. This thioflavine-T reactivity or fluorescence shows no particular pattern in either tumor, occurring both within tumor cells and in the adjacent connective tissue stroma.

The thioflavine-T technique is considered superior in the demonstration of amyloid. It is more sensitive than congo red or methyl violet. However, it is important to emphasize that this technique is not diagnostic for the presence of amyloid. Other substances will show thioflavine-T positivity, such as fibrous proteins, mucopolysaccarides, and mucoproteins. Therefore the finding of thioflavine-T positivity in these tumors in no way identifies the substance as amyloid; it may be merely an amyloid-like mucopolysaccaride or mucoprotein.

School of Salernum

Now if perhaps some have desire to know,
The number of our bones, our teeth, our veines,
This verse ensuing plainly doth it show,
To him that doth observe, it taketh paines:
The teeth thrise ten, and two, twise eight arow.
Elev'nscore bones save one in us remaines:
For veines, that all may vaine in us appeare,
A veine we have for each day in the yeare:
All these are like in number and connexion.
The difference growes in bigness and complexion.

—Regimen Sanitatis Salerni

Editor's note: The School here asserts that we humans are all anatomically alike, with 32 teeth, 219 bones, and 365 veins. We differ only in size and color. This must have been the origin of our more modern memory devices: "On old Olympus tip top a fat . . ." for the cranial nerves; and "Never lower Tillie's . . ." for the bones of the wrist; and "As she lay extended Sir Oliver . . ." for branches of the carotid artery. I am sure you all recall them.

Sympathy

Fashionable New Yorkers in the seventeenth century felt obliged to maintain their prestige, when sick in bed, not only by calling a physician but also by employing the services of two "comforters" whose incredible occupation was to comfort the patient throughout the long hours of the night. Dressed in black and having a funereal expression, these cheerful chaps sang mournful hymns, read sad parts of the Bible, and discussed death and the Hereafter. By dawn, the patient was usually hoping for the worst.

—Freling Foster, Collier's

The Skin Moves

In spite of his young age a twenty-year-old railway worker was stricken with an ailment oftener met in older men. It was a varicose vein of the hip. The youth was brought to the clinic with complications caused by an operation he had had three years before. On that occasion a section of the enlarged vein was removed from the right hip and knee. It had been expertly done, but the postoperative wound did not heal. A large, incurable ulcer appeared. It was this ulcer that brought the railwayman to the clinic.

The doctors saw plainly that the usual treatment would be useless in his case.

They picked a section of skin near the shoulder-blades. It was a rectangle about 5 inches long and 2 inches wide. But the skin was not cut out. It was incised along the two long sides of the rectangle. A thin surgical knife was used to pare it off, and separate it from the underlying tissue. A flap of skin was thus produced, which was connected with the body by its two unincised edges—the short sides of the rectangle.

The surgeon took a needle and silk thread. He folded the two incised edges inward and sewed them together, obtaining a miniature cylinder which was much like the round grip of a suitcase. Sewed up in this way the bleeding inner surface of the flap of skin was protected against infection.

The skin flap did not necrose. Nutrition reached it by the unsevered blood vessels of the two unincised edges of the rectangle.

An incision along one of these edges detached the oblong roll of skin from the body. It no longer resembled a suitcase grip, and took on the appearance of a rounded, pliant stalk, easily bent in any direction. The stalk was ready to start on its journey.

The length of the stalk was measured off along the patient's back in the direction of the affected leg, and an incision made there. The top of the stalk was then bent over, fitted into the incision, and secured in it. In several days it took root.

That was how the flap of skin made its first 5-inch step.

After some time the skin flap was able to make its second step. The second short edge of the rectangle was detached from the body, and made something of a cartwheel to arrive at a new incision prepared for it another length away.

Advancing in this manner along the route mapped out for it by the surgeon, the skin made its journey from the shoulder-blade to the hip, and on to the right knee. Its free end was stitched into the incision made just above the edge of the ulcerated site.

The skin flap had thus reached its destination. That was the final stage of its journey as a "suitcase grip." Now for the final stage of the operation. The farther end of the "grip" was cut off. The stalk-like skin roll stood rooted in the incision on the ulcer border. The sutured side was then incised, and the "stalk" unrolled into a rectangle again. The ulcerating scar on the operation site had been removed and there was a wound in its place. The spread-out "stalk" was placed upon it. The new skin took its designated place, and sutures secured it for good. The transplantation was over.

Today both the initial and improved forms of the operation are known throughout the world as the walking stalk operation. It was evolved by Academician Filatov, the Russian oculist.*

Plastic Operations on the Fallopian Tubes

THOMAS A. STARKEY, M.D.*
TIFFANY J. WILLIAMS, M.D.†
Rochester, Minnesota

THE WRITINGS of Galen suggest that the uterine tubes were known to Herophilus about 300 B.C.; and Ruphus of Ephesus, writing at the end of the first century A.D., noted the presence of these tubes in women, but seems to have regarded them as suspensory structures. Galen in his second-century treatise on gynecology described the uterine tubes in some detail, recognizing for the first time the communication between the tubal lumen and the uterine cavity. It remained for Gabriele Fallopio to provide the first accurate description of the human oviduct in his *Observationes Anatomicae*, published in Venice in 1561:[1]

> That slender and narrow seminal duct rises, . . . from the horns of the uterus itself; becomes, when it has gone a little bit away, appreciably broader, and curls like a branch until it comes near the end, . . . and its end is torn and ragged like the fringe of well-worn garments, and it has a wide orifice which lies always closed through the ends of the fringe falling together; and if these be carefully separated and opened out, they resemble the orifice of a brass trumpet.

The term "fallopian tube" has been universally accepted since the time of Fallopio; it has reached the zenith of eponymic‡ acceptance in medical and anatomic literature, being spelled with a small f.

Surgical procedures on the fallopian tubes include three main types of reconstructive operations: salpingostomy (including salpingolysis), resection with end-to-end anastomosis, and resection with uterotubal implantation. The first case reports appeared during the latter part of the 19th century, when adnexal surgery was being developed. Martin,[2] in 1885, reported the results of the first salpingostomy; in 1894 Mackenrodt[3] noted two successful operations; and in 1900 Goullioud[4] reported a review of the procedure with appropriate drawings. In 1896 Watkins[5] noted a case of successful uterotubal implantation; and Turck[6] in 1909 told of two successes in eight cases of uterotubal implantation.

Plastic tubal operations continued to be done in small numbers through the years, but with such poor results that in 1937 a questionnaire by Greenhill revealed that 56% of the gynecologists condemned the operation.[7] Some improvement in the results of these procedures is evident though, since the advent of the antibiotic era in the late 1930's and since the introduction of polyethylene tubing and Silastic hoods in the early 1950's.

Experimentally, the allantoic membrane was used in humans in the early 1940's in an effort to prevent fimbrial adhesions; tubal patency was obtained in a relatively high percentage, but the conception rate was very poor.[8] Various other ideas have been tried experimentally in lower animals, without much success. These include the use of catgut, bone wax, whalebone filament, and silver wire as stents; the use of resected arteries and veins in place of the fallopian tube;[9] and the use of ileum as a substitute oviduct.[10,11]

O'Neill[12] in 1964 employed the vermiform appendix of a young woman to replace one of her totally fibrosed and occluded oviducts. The organ was patent eight weeks after surgery, but no pregnancy had occurred by the time of his report in 1966.

A device designed to staple the fallopian tube has been reported in the Russian and the English literature.[13] It has been used experimentally in rabbits and dogs, and shows some promise if the technical problems can be overcome.

Anatomy and Histology of the Tube

Anatomically, the fallopian tube is divisible into four parts: the interstitial portion, traversing the muscular wall of the uterine cornua from which the tube arises; a narrow isthmus adjacent to the uterus; the ampulla, which is the widened middle and outer third of the tube; and the fimbria, or infundibulum, representing the outer portion of the tube.

Histologic examination of the fallopian tube reveals three layers: an outer serous layer, a middle muscular layer, and an inner mucous membrane. This inner membrane, known as the endosalpinx, is composed of three types of cells: ciliated, nonciliated secretory, and the intercalary peg cells. The presence of endometrium in the tubal lumen is not uncommon, being found perhaps in as many as 10% of women. The chief significance of this anomaly is in its possible bearing on the etiology of tubal occlusion. The cells of the endosalpinx are influenced by ovarian hormones, and they undergo a histologic cycle corresponding to the various phases of menstruation. The endosalpinx is arranged in longitudinal folds, or rugae, and these rugae divide and subdivide in the more distal portions of the tube, so that a cross section at the fimbriated end reveals a highly aborescent configuration.

Physiology of the Tube

Tubal function was studied by Westman[14] through an "abdominal window" in the rabbit. He found that at ovulation the fimbria are significantly hyperemic, edematous, and distended as they come into direct contact with the ovary. Doyle[15] has taken motion pictures of the ovulatory process via the cul-de-sac; he observed that once the ovum is within the tube, a twofold mechanism propels it toward the uterus: tubal muscle peristalsis and ciliary motion of the endosalpinx. Certain segments of the tube may show antiuterine movement though, and this is believed of importance in establishing union between sperm and ovum somewhere in the distal portion of the tube.

Recently, Pauerstein, Woodruff and Zachary[16] have published a thorough review of tubal physiology, which demonstrates ". . . that the oviduct is not a mere conduit for ova and sperm, but in truth is an organ of exquisite function."

Etiologic Factors

Salpingitis is the etiologic factor in most cases of tubal occlusion, but pelvic adhesions or pelvic scarring, caused by appendicitis or endometriosis, may be the etiologic factor in some cases. The common bacterial causes of salpingitis are gonococcus, streptococcus, staphylococcus, and tubercle bacillus. The gonorrheal type of salpingitis is an ascending infection, causing first an endosalpingitis, then inflaming the other tubal layers as well. If allowed to run its natural course, this type of salpingitis usually leads to partial or complete tubal occlusion. Pyogens, however, make their way outward via the lymphatic channels and blood vessels of the parametrium and broad ligaments. Pyogenic salpingitis is usually associated with postpartum or postabortion infection, rarely with cervical cauterization or uterine curettage. The enlargement of the tube in this type of infection is much greater than with gonococcal salpingitis, but this enlargement is due to interstitial involvement rather than to distension of the lumen. The relative immunity of the tubal mucosa to the pyogens explains the far more favorable prognosis for conception.

Pyosalpinx, hydrosalpinx, and salpingitis isthmica nodosa represent chronic forms of the disease. The first two are sequelae of gonorrhea in most cases, although they may also occur after tuberculosis. Salpingitis isthmica nodosa is also probably of inflammatory origin, although some believe that it results from a process resembling adenomyosis of the uterus; still others have suggested that these lesions represent endometriosis of the tube.

Evaluation

Before reconstructive tubal surgery can be considered, a careful workup of the infertile couple is mandatory. When the husband is known to be fertile, when the results of endocrine and ovulation studies are normal, and when repeated tubal insufflation or hysterosalpingographic studies indicate occluded fallopian tubes, then surgery may be contemplated.

A history of treated gonococcal disease is of importance because most untreated patients and patients with recurrences will have massive adhesions in a rather fixed pelvis, if not tubo-ovarian abscesses. Adequate treatment tends to result in fewer and more filmy adhesions, and hence a better prognosis. A history of appendicitis is also of importance, because this disease, even when it has occurred in the very young, is frequently followed by pelvic adhesions affecting the fimbria. In the Mayo Clinic series,[17] approximately 75% of the patients who underwent reconstructive tubal surgery had previous intra-abdominal or intrapelvic manipulation under a physician's care. Included among these were nine patients who admitted to intra-uterine manipulation in successful efforts at abortion; 14 who had undergone appendectomy presumably for acute appendicitis; and five who had had tubal ligation.

The opportunity for an emergency salpingoplasty may present at any time, when the physician is astute enough to diagnose an early, unruptured ectopic pregnancy. Depending on the condition of the tube at surgery, the conceptus may simply be expressed from the fimbriated end, salpingostomy may be performed, or possibly resection and re-union of the tube.

Operative Principles

Siegler and Hellman[18,19] have stated that it is the burden of the surgeon to devise, at laparotomy and in accordance with the gross abnormality of the tubes, the most logical procedure to produce function. Not surprising then is the large percentage of cases in most recent series that have involved a combination of procedures. Siegler also has made a plea for more uniform recording of the facts in each case,[20] for the sake of better comparison of results in the various series. Mulligan[21] suggested that, if only one adnexus seems reparable, this side should be improved as much as possible and the other adnexus excised in order to secure constant function of the former.

Shirodkar,[22] who perhaps has more experience at tubal plastic surgery than anyone else in the world, has recently outlined some factors affecting prognosis. He said that the results of salpingostomy are better when the uterus is well developed; when adhesions are flimsy and easily separable; when the hydropic fallopian tube returns to near normal size and color, and when the walls of the tube become soft throughout its length. When the fimbria are of normal length and character, the results of salpingostomy may be good; but when the fimbria are distorted or absent, the outlook is poor to dismal. Because a viable tubal ciliary epithelium can be expected with hydrosalpinx of grade 1, the prognosis after tuboplasty is reasonably good.

Operative Procedures

Fimbriolysis and Salpingolysis

The technique consists of gently elevating the fimbrial end of the tube, separating away any thin bands or veils of peritoneum, and at the same time making every effort not to cause bleeding. Adhesions may be separated with fine scissors, by opening the blades of long tissue forceps between the adhesions, by gentle pressure with a gauze sponge, or by division with a cutting cautery. Bleeding may be controlled with hot saline, very fine catgut ties, or cautery, or in some instances by the use of a hydrocortisone rinse.

Salpingostomy

In this procedure the dilated tube is reopened at the fimbria, ampulla, or isthmus. The site is chosen so that the artificial opening in the tube lies in the best possible relationship to the ovary, in order to facilitate entry of an ovum into the tube. There has been little actual change in technique since the turn of the century: an incision is made into the tube, proximal patency is demonstrated, and the mucosa is then everted by numerous interrupted sutures of fine catgut, nylon, or braided silk. The end result may take the form of a cuff, simple stoma, or fishmouth. Again, all bleeding points must be meticulously controlled. Polyethylene tubing may be used as a splint to keep the newly formed stoma open, or a Rock-Mulligan hood made of Silastic may be employed. The polyethylene splint is generally removed in six weeks; the Rock-Mulligan hood requires a second operation, approximately three months later, for removal. Shirodkar[23] recommends tubal irrigation with a solution of penicillin and hydrocortisone at frequent intervals during the first few postoperative days, then every four days until three weeks after the operation. He believes that this method can keep the newly formed stoma open.

Anastomosis

In this procedure the blocked portion of the tube is located and excised, and anastomosis in two layers is accomplished with fine interrupted sutures. Polyethylene tubing is frequently used as a splint, then removed in about six weeks. The point of obstruction may be easily located, according to Siegler,[18] by using a cervical isthmic occlusive clamp and injecting indigo carmine via the fundus. The dye proceeds to the point of obstruction, and when this is relieved, the dye can be readily seen to emerge from the transected end of the tube. The blocked portion also may be located by tubal irrigation, or probing from the distal end. The "pure" anastomosis operation is useful primarily in cases of previous surgical sterilization.

Uterotubal Implantation

The implantation operation has many variations and is often part of a combined procedure. The technique most commonly employed today was reported first in 1932:[24] the tube is divided at the point of obstruction, the occluded cornual portion reamed out, and the patent residual tube pulled into the uterus and held there by sutures.

As Pratt and associates[25] describe their technique, the tube is first irrigated with saline to determine whether any obstruction exists distal to the cornua. After the tube is divided and the lumen is rechecked, the medial end is split and fine catgut sutures are stick-tied to each side. An opening is then made through the uterine cornua into the endometrial cavity either by reaming with a 5-mm punch, or by coring with a narrow-bladed scalpel. The blunt end of a large, curved needle is then passed into the uterus posteriorly and out the newly formed opening. The needle is threaded, and the suture is pulled through the posterior uterine wall. This process is repeated anteriorly; then by means of gentle traction, the fallopian tube is pulled through the uterine horn into the endometrial cavity. The newly implanted fallopian tube is then fixed externally by several sutures from the tubal serosa to the uterine wall.

Results

The results of plastic operations on the fallopian tube are generally discouraging—in terms of patency, conception, and live births. In 1960, Puigmacia[26] compiled and reviewed the results obtained by 66 surgeons who had done approximately 3,000 operations (Table 1). The incidence of ectopic gestation in this review was 2.68% with a slightly lower incidence in the cases in which polyethylene was

not used.

A number of series have been reported since 1960. Because of a lack of uniformity in evaluation, technique, and follow-up, it is not possible to make useful comparisons. Siegler and Hellman[19] in 1963 reported a critical analysis of their 43 cases (Table 2). Mulligan[21] reported his results from salpingostomy in 1966; he employed the Rock-Mulligan hood in all cases (Table 3). He advised that the prosthesis be removed by laparotomy, not via the cul-de-sac, at least 12 weeks after the operation.

Mroueh and associates[27] reported the Yale Medical Center experience with 40 infertile patients undergoing surgical treatment of tubal occlusion or pelvic adhesions (Table 4). They pointed out that only two term pregnancies occurred among the 32 patients who required bilateral surgery. The best results were obtained with patients needing only lysis of adhesions; among those with implantation operations, no pregnancies occurred. It is their belief that significant improvement in the results of tubal surgery will not come from further refinement in technique, but must come from increased knowledge of tubal function and physiology so that a more rational selection of cases for surgery can be made.

Hanton, Pratt, and Banner[17] reviewed the Mayo Clinic experience with tubal plastic surgery from 1945 through 1962, a total of 75 patients (Table 5). Fifty-four of these patients were studied in the immediate postoperative period for tubal patency; 74% had patent tubes. But when these patients were restudied from one month to 10 years later, the percentage dropped to 55%. Antibiotics were used preoperatively in some but with no great increase in the success rate. Polyethylene splints were used in only five patients, but no pregnancies occurred; Rock-Mulligan hoods were not used in any patients in this series. The presence of obvious hydrosalpinx or pyosalpinx in those patients who had salpingostomy appeared to be a poor prognostic factor.

Conclusion

The objective of plastic operation on the fallopian tube must be to achieve some semblance of normal function, not merely to achieve patency. Israel[28] reminds us that the fallopian

It's the Law

NO LIABILITY FOR ELECTROSHOCK THERAPY INJURIES

A 74-year-old patient was diagnosed as suffering from manic depressive psychosis and was hospitalized for electric shock treatments.

During the second treatment, a cracking sound was heard. It was later determined that she had suffered bilateral fractures of the acetabula.

Since fractures are a recognized risk with electric shock therapy, the mere presence of the fractures was not evidence of negligence.

Pendleton v. Burkhalter, 432 S.W. 2d 724 (Tex., May 16, 1968: on rehearing, September 5, 1968: rehearing denied, October 24, 1968). The Citation, Vol. 18, No. 8, February 1, 1969.

Tough Treatment

An old lady fell down the stairs and broke her leg. The doctor put it in a cast and warned her not to walk up and down the stairs. The leg was slow in mending. Finally, after six months, the doctor announced it was all right to remove the cast.

"Can I climb the stairs now?" asked the old lady.

"Yes," answered the medical man.

"Oh, I'm so glad," she chortled. "I'm sick of climbing up and down the drainpipe all the time."*

Corrosive Esophagitis*

ARVID F. JOHNSEN, M.D.†
ARNDT J DUVALL, III, M.D.†
Minneapolis, Minnesota

DESPITE PUBLIC EDUCATION efforts and the labeling of poisons, there remains a large number of patients seen annually with severe caustic burns. The great majority of these patients are children under the age of five years who have accidentally ingested a potent caustic. Often the severely burned are at least mildly mentally deficient or have neglectful parents. Adults ingesting corrosive agents usually do so in a suicide attempt. Rarely is homicidal intent implicated.

Treatment includes immediate life-saving care and often long-term management of a permanently altered hypopharynx and esophagus. The most common areas of severe burn are the esophageal introitus, the aortic knob area, and the esophagogastric junction.

In severe corrosive burns, the larynx and stomach may also be involved[3].

Caustic Agents

Lye is the most devastating caustic agent ingested by man. Unfortunately, when in solution, it has a white color, and children may mistake it for milk. Drano and Sani-flush, commercial agents found in nearly every home, are also capable of producing severe burns. Less frequently ingested, and somewhat less potent, are phenol, lysol, potassium permanganate, and the strong acids. Acids have a tendency to coagulate the superficial layers of the esophagus, forming a firm eschar which limits deeper burning. The acids, however, may cause serious gastric burns[8]. Clorox ingestion has been found to cause little damage to the oral mucosa and esophagus, prompting several investigators to challenge the need for esophagoscopy and treatment of these patients[5].

Diagnosis

The history is usually vague concerning the amount of material ingested, making judgment

Presented to The Minnesota Academy of Ophthalmology and Otolaryngology December 13, 1968.

†Department of Otolaryngology, University of Minnesota.

on history alone unreliable. It is helpful if the agent ingested is brought with the patient. Careful physical examination of the mouth for evidence of burns is mandatory. While a severe esophageal burn may co-exist with an unburned mouth, this is an unusual circumstance occurring when a dilute solution does not penetrate the oral salivary coating. Contrariwise, oral burns often, but not always, are associated with esophageal burns. Waggoner[8] found that eight of 43 patients with mouth burns had esophageal burns requiring treatment; Cody[1] found that 12 of 23 mouth burns showed associated esophageal injury.

The diagnosis of esophageal burns ultimately depends on endoscopic findings. While endoscopy should be done as soon as the patient's general status permits, it is wise to wait approximately 24 hours post injury to allow development of recognizable eschar and ulceration. Immediate esophagoscopy may reveal only erythema and edema. The esophagoscope is advanced only far enough to establish the diagnosis of a severe or circumferential burn and is then withdrawn. Further advancement is hazardous. The hypopharynx and larynx are closely inspected for evidence of burns.

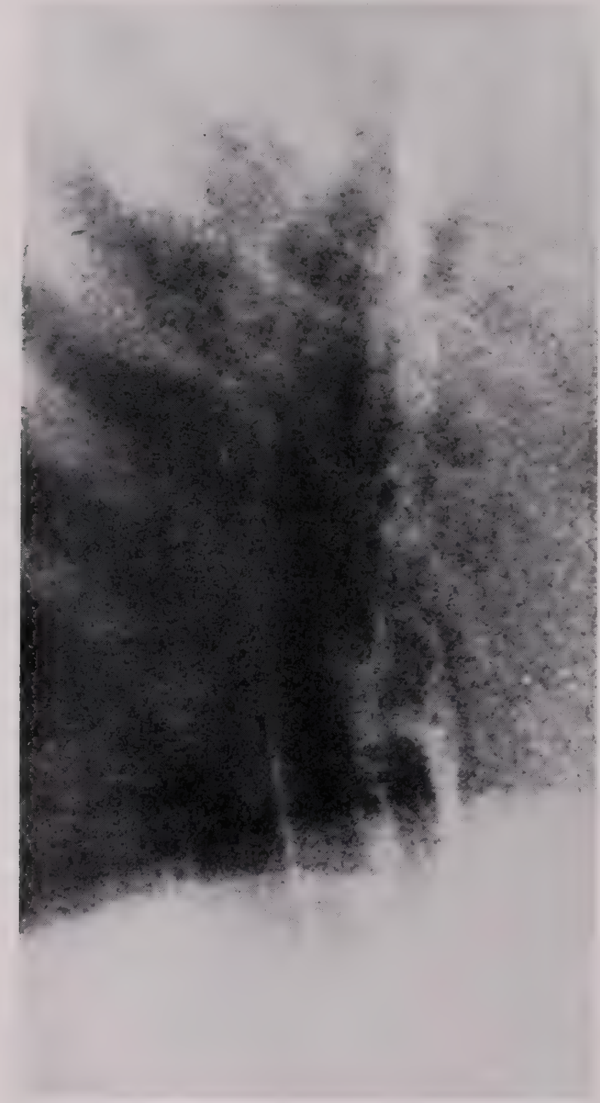

Fig. 1—Case 1. Aperistaltic dilated esophagus eleven days post lye ingestion. Patient receiving steroids.

Pathology

An excellent experimental study on dogs by Johnson[4] has defined three phases in the course of corrosive esophagitis.

The Acute Phase

The acute necrotic phase occurs one to four days post injury. There is death of cells secondary to coagulation of intracellular protein. Vessel thrombosis and bacterial infiltration is seen.

Ulcerative-Granulation Period

The ulcerative-granulation tissue phase follows the slough of superficial necrotic coagulated tissue at three to five days. This leaves an acutely inflamed ulcerated lesion which by the end of the first week is covered with fresh superficial granulation tissue containing blood vessels and fibroblasts. Collagenous connective tissue is seen at 10 to 12 days.

Stricture

Cicatrization and stricture formation may be noted by three to four weeks when collagenous material begins to contract. The superficial inflammatory tissue progresses slowly until four to eight weeks when reepithelialization occurs. It is during the second month that clinical vigilance is necessary to pick up early stricture formation.

Treatment

As early as 1950 cortisone was reported to exhibit an anti-inflammatory effect and inhibit fibroplasia in wounds.[6] This stimulated interest concerning its use in esophageal burns. Since bacterial invasion is also seen following burn injury, it was postulated that antibiotics might also be useful. Johnson's experimental study on dogs with burned esophagi included the use of antibiotics and steroids alone and in combination. He found that the use of antibiotics alone promoted early granulation tissue formation and hastened its maturation. This resulted in *earlier* stricture formation.

Steroids alone prevented much of the early inflammatory reaction, repressed the granulation tissue response, and inhibited fibroplasia. The incidence of narrowing and stricture formation was much less than in the control animals and those treated with antibiotics alone.

The animals treated with both antibiotics and steroids showed the lowest incidence of stricture and the least inflammatory reaction.

Delayed institution of steroid therapy beyond two to six days post ingestion was not as efficient in preventing the intense inflammatory response and later stricture.

From these studies we may extrapolate useful guidelines for the treatment of patients ingesting corrosive substances. For convenience, treatment will be divided into immediate, intermediate, and long-term.

Immediate Treatment:

Severely burned patients are often in shock and require supportive measures. Intravenous fluids, including blood or other volume expanders, may be necessary. Intraoral, hypopharyngeal, and laryngeal edema may compromise the airway, necessitating tracheostomy. Vomiting is not induced, as it is always too late and may cause further injury. Likewise, the use of mild acids to neutralize the strong base is too late.

Esophagoscopy should be done between 12 and 24 hours post ingestion to establish the diagnosis of esophageal burn. This timing seems appropriate because it is delayed long enough to permit the development of recognizable pathology and yet provides an early diagnosis which dictates the therapeutic regimen. Diagnostic esophagoscopy at seven to 10 days may constitute an unwarranted delay if the burn was not suspected and no treatment had been given. In addition, the burned esophagus is weakest at that time, making the procedure more hazardous.

Once the diagnosis of esophageal burn is established, the patient should swallow a heavy # 4 or D button-hole twist braided silk string. The proximal end is brought out through the nose and either taped to the head or looped around the ear. This string serves as an important guide for later antegrade or retrograde dilatations. If the burn is severe, a gastrostomy should be done, permitting retrograde dilatations and feedings. In this case the distal end of the swallowed string is brought out the gastrostomy opening and tied to the proximal end of the string, creating a continuous loop. Irritating nasogastric tubes may contribute to the inflammatory response and are best avoided.

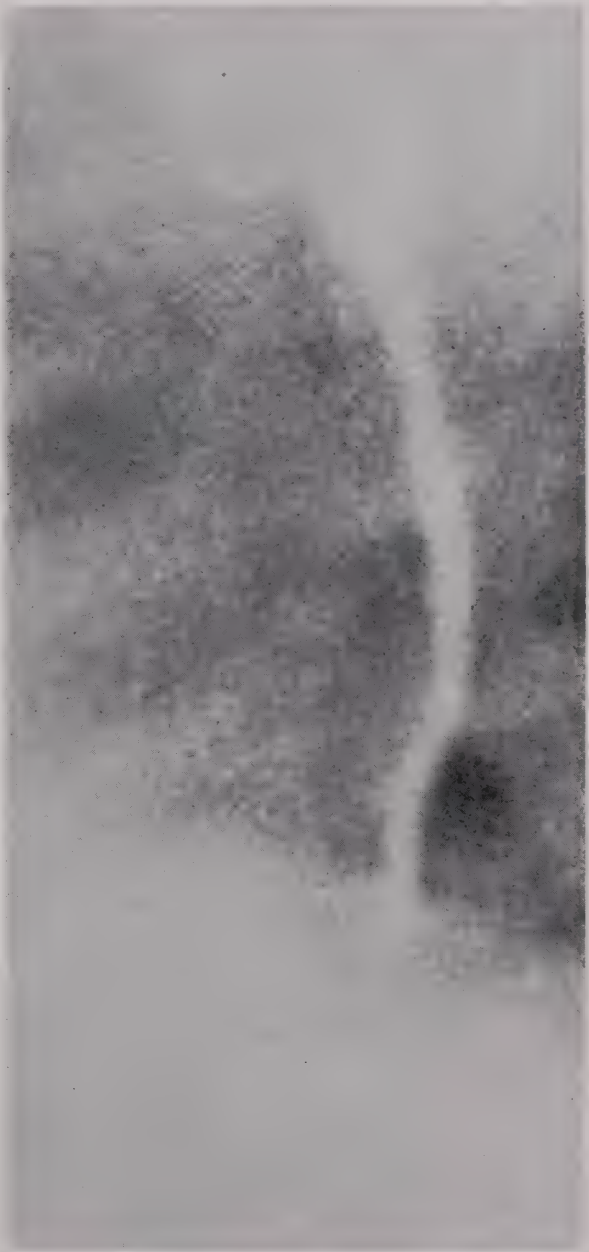

Fig. 2—Case 1. Diffusely narrowed esophagus twenty-one days post lye ingestion and three days following cessation of steroids.

Antibiotics and steroids are begun when the diagnosis is established, provided there are no definite contraindications such as tuberculosis or peptic ulcer disease. The dosage of prednisone in a 70 kg man is 20 mgm qid, tapered down to 5 mgm qid over seven to 10 days. Children are given one half the adult dose. Antacids are given routinely. Oral burns can be comforted by use of bismuth subcarbonate powder. Children will tolerate this if it is sprinkled on marshmallows.

Intermediate Treatment:

Antibiotics may be discontinued after two weeks since their major role is to decrease the inflammatory response secondary to early bacterial invasion. Steroids are continued at a maintenance level for eight weeks, since the epithelialization may not occur until that time.

Esophageal Bouginage or Dilatation

The role of bouginage* and when it should be started have never been clearly resolved. Advocates of early bouginage[2] feel that the prevention of stricture formation outweighs the risk of perforation during this time when the burned esophageal wall is at its weakest. Others[7] feel that early dilatation is too hazardous and that later bouginage is adequate.

Blunt Dilator

The simplest method is peroral passage of a blunt rubber mercury-filled Hurst dilator. While following the path of least resistance has great application in well-established esophageal strictures, this feature is undesirable and dangerous in an acutely burned esophagus with weak walls, pocketing, and irregularities. For this reason the Hurst dilator is rarely used in the acute situation and is reserved for management of the chronic strictures.

Dilator Over String

Peroral passage of a dilator (e.g., Sippy, Peustow, Plummer) over a previously swallowed string, while safer than the blind passage of dilators, does not entirely eliminate the possibility of the dilator tip being imbedded in a pocket in the esophageal wall. This type of dilatation avoids the need for a gastrostomy; however, it should never be used if the patient has a gastrojejunostomy, as the string may loop around and strangulate the gut.

Retrograde Dilatation

The safest method is retrograde dilatation via gastrostomy. Gastrostomy should be done early so that healing occurs by the time dilatation is started. Dilatation is accomplished by passing consecutively larger, tapered Tucker dilators through the gastrostomy, up the esophagus, and out through the mouth. The dilators are tied together end to end with an intervening length of heavy, black silk at least as long as the distance from the gastrostomy to the mouth. Since tension can be kept on the string at both the gastrostomy site and the mouth as the dilators are being passed, there is no danger of perforation by false passage. Its greatest application is in the early and intermediate treatment of burns.

While not trying to avoid this issue, we feel that each case must be individualized, and if early dilatation is felt to be necessary, it should be done in the safest manner possible, namely, retrograde dilatation via a gastrostomy using Tucker dilators. For lesser burns, antegrade dilatation begun at a later, safer date is felt to be adequate.

Periodic esophograms beginning two to three weeks post ingestion are of value in determining the extent of scarring and whether any circumferential scarring has occurred.

Long-term Treatment:

Many patients will require periodic bouginage for several years or for life. A schedule is determined which achieves and maintains an adequate esophageal lumen between dilatations. This can vary from a day to months. Antegrade Hurst dilators are most frequently used and many patients can manage this at home.

There are some patients who cannot be successfully dilated by this method because of complete stenosis, scarring with marked pocketing and irregularities; or because they refuse dilatations.

Surgical excision of the strictured area or bypass via an esophagocologastrostomy or pharnygocologastrostomy is the current surgical treatment of choice.

Sudden difficulty with dilatations or increased dysphagia should alert the physician to a possible neoplasm in the esophagus.

---

Case Reports

These cases were selected to illustrate the great disability that a severe burn can cause and the immediate and long-term treatment necessary in their care.

Case 1:

This two-and-one-half-year-old retarded boy ingested "Lewis Lye" on August 9, 1965. He was treated in an emergency room in South Dakota with oral milk and "gastric lavage." Later the same day he was transferred to University of Minnesota Hospital. On examination he was found to be acutely ill with first degree burns on his anterior thorax and abdomen. Supportive measures, including intravenous fluids, were instituted, and Solu Cortef 40 mg intravenously q6h was begun. Aqueous penicillin 600,000 u q6h and chloromycetin 250 mg q6h were started. Because of respiratory distress from laryngeal edema, a tracheotomy was performed in the operating room that same day. Examination there revealed burns of the tongue, lips, bucco-alveolar gutters, soft and hard palate, epiglottis, and right aryepiglottic fold. The vocal cords appeared normal. There was evident coagulation necrosis of the esophageal introitus, and the esophagoscope was not passed further. A gastrostomy was performed on August 11 for purposes of feeding and dilatation. Several days later the patient swallowed a string which was then pulled out through the gastrostomy opening. A cine esophagram, August 20, (Figure 1) showed a dilated esophagus exhibiting poor peristalsis. The penicillin and chloromycetin were discontinued August 20, and the patient was tapered off steroids by August 27, because of a mumps epidemic on the ward. A repeat study on August 30 (Figure 2) revealed severe diffuse narrowing below the aortic knob. Retrograde dilatation was begun August 31, as soon as the results of the latter cine esophagram were known. Biweekly or weekly retrograde Tucker dilatation was done until early October 1965 when antegrade Hurst dilatation was started. The tracheotomy was also discontinued at that time.

Since November 1, 1965, the mother has dilated the patient at home with a #24 F Hurst dilator. Except for two episodes of obstruction requiring retrograde dilatation in the hospital, she has managed this successfully. In January of 1967, the gastrostomy was removed.

This case represents the average *severe* burn, i.e., one requiring emergent supportive and long-term care. The points of special interest are the initial cine esophagram which showed dilatation 11 days post ingestion and the esophagram 21 days post ingestion that revealed a marked narrowing of the esophagus. It should be noted that steroids had to be discontinued 18 days post ingestion. Our present regimen includes steroids for up to two months or until such a time as esophagoscopy shows re-epithelialization of the esophagus.

One should not be encouraged by an esophagram showing dilation, since this merely precedes later stricture if there are raw surfaces or areas of incipient fibrosis and scarring.

Case 2:

This two-year-old boy was first seen at Ancker Hospital in November 1964 for Drano ingestion. The initial laryngoscopy revealed extensive burns of the entire oropharynx and hypopharynx. The larynx was also felt to be involved. Treatment consisted of tracheotomy, gastrostomy, steroids, penicillin, chloromycetin, and early retrograde dilatation. He was transferred to University of Minnesota Hospitals in April 1965 because of repeated aspiration pneumonia. Examination revealed a severely scarred hypopharynx which was funnel-shaped and directed into the glottis. Because all secretions and oral fluids were directed straight into the glottis, a laryngectomy had to be performed. Since that time the patient has required retrograde dilatations which are presently done biweekly. He is able to swallow his oral secretions and small amounts of liquids. His major nutrition must still be supplied via gastrostomy feedings. The possibility of learning esophageal speech is remote because of the severe oral and esophageal scarring.

This case represents perhaps the ultimate tragedy short of death attendant on ingestion of a caustic. The hypopharyngeal and oral scarring prevent successful esophagectomy and bypass procedures. The laryngectomy, while life-saving, rendered him speechless.

Summary

The accidental ingestion of corrosive substances continues to be an all too common tragedy in the pediatric age group. Diagnosis is dependent on careful physical examination and esophagoscopy. Based on experimental studies and clinical series, the early use of antibiotics and steroids reduces the inflammatory response and appears to prevent or minimize later stricture formation.

Dilatation is often necessary in the treatment of chronic strictures, and its early use may play a role in the prevention of permanent stricture. Occasionally, surgical removal of isolated areas of stricture formation or bypassing a severely burned esophagus is indicated. Intelligent, individualized early management and long-term care are requisite in the complete care of these patients. Public interest in the problem should be aroused, as preventive medicine is crucial.

Famous Men and Their Bad Health

"Here I Stand"

Martin Luther

"The just shall live by faith!"

This was Martin Luther's unqualified declaration after a flash of sublime insight released him from his commitment to corrupt Catholic doctrine.

Only through the prism of his Olympian soul struggle and cataclysmic spiritual revolt can we assess the man health-wise. Never rugged physically, weakened by stern monastic asceticism, plagued by numerous chronic ailments, prematurely old and overweight, haunted by imaginary guilt and remorse, pursued by delusions—all under the shadow of heresy: these formed the constellation of Luther's infirmities.

Though Luther was probably not neurotic, his early physical symptoms were of a "nervous" character: dizziness, head noises, stubborn constipation, urine retention, insomnia. In fact, he ruefully called himself a Lazarus. Of his constipation he once wrote to a friend: "The trouble with which I suffered at Worms has not left me but increased, for I am more constipated than ever in my life and despair of a remedy. The Lord thus visits me that I may not be without a relic of the cross. Blessed be He. Amen." From this we can deduce that Luther regarded illness as divinely ordained—if not actually imposed.

In addition, there was profound dejection at his failure to measure up to the lofty stature he thought God expected of him. Here he was sure that the Devil was sabotaging his efforts. Sometimes when Luther was concentrating on his studies, Satan, with deliberate malice, made so much noise by pounding on the walls or rattling nuts in a can that Luther was obliged to abandon his books and retire.

While Luther believed sickness was God-ordained, he was too practical to spurn materialistic medication. On one occasion during his youth when he was confined to bed with a raging fever and was denied liquids—as was customary then—he crawled unseen to a pail of water and drank himself full, a measure which induced abundant sweating and probably saved his life. During another severe illness he repudiated an invalid's vapid diet, called instead for fried herring and cold peas, consumed them, and was none the worse for his indiscretion—if indiscretion it was. On a later occasion, during an agonizing kidney-stone attack away from home, his wife wrote to him recommending a mixture of garlic and horse dung. Unabashed by the revolting concoction, Luther swallowed it, then tersely wrote his wife: "Your medicine did not help me."

One of Luther's biographers, Ewald Plass, gives this stark and succinct resume of Luther's ailments: "Luther, from his fortieth year onwards, was a sick man. After he had suffered for six months, in 1521, from severe digestive troubles, he was attacked in 1523 by a nervous affection of the head, which soon became permanent. In 1526 he developed a severe stone in the kidneys, with all possible accompaniments—feverish rheumatism, sciatic conditions, boils, etc. In addition to this he suffered very frequently from obstinate catarrh and digestive trouble, also, transitorily, from hemorrhoids (1525), dysentery (1528), a running inflammation of the ears (1527), which for weeks deprived him of sleep and hearing, toothache, and fearful nervous constriction of the chest (1527)."

Luther died of a heart attack in 1546, at the age of 63.

To read Luther's life is both exhausting and exalting: exhausting as we endure vicariously with him his manifold physical morbidities and spiritual torments, and exalting as we identify with him in his victorious transcendence of both.

Only in such Titanesque world figures as Martin Luther does the immortal spark so illumine the mortal clay as to triumph over it so gloriously!

With acknowledgments to Ewald Plass: This Is Luther, 1948.

Tumors of the Upper Lip

Benign and Malignant

FAWZI N. ABU JAMRA, M.D.*
JOHN B. ERICH, M.D.†
LEWIS B. WOOLNER, M.D.‡
Rochester, Minnesota

Because of their infrequent occurrence, tumors of the upper lip seldom have been studied separately; instead, they have merely been included in reports on tumors of the lower lip, oral cavity, salivary glands, and skin. However, since some growths on the upper lip present distinctive features, detailed consideration of them seems worthwhile. Consequently, we reviewed the clinical and pathologic characteristics, the treatment, and the prognosis of tumors involving the upper lip, which have been seen on our service at the Mayo Clinic.

Materials and Methods

The records of all patients with benign and malignant lesions of the upper lip who were examined at this clinic from 1944 to 1963 inclusive were abstracted. After exclusion of cases in which tumors originated in adjacent tissues and invaded the upper lip by direct extension, 702 cases remained. Except for 133 angiomas treated without microscopic confirmation, diagnoses were definitely established by reexamination of the original microscopic sections. When slides were not available, paraffin blocks of preserved tissue were prepared and additional sections were made. Follow-up information on each patient was acquired through return visits to this clinic or by direct correspondence.

Results

The 702 tumors, 272 (38.7%) benign and 430 (61.3%) malignant, were fairly evenly distributed between the sexes (Table 1). Of patients having benign lesions, 145 (53.5%) were female and 127 (46.7%) male; of those having malignant lesions, 235 (54.7%) were male and 195 (45.4%) female.

Benign Lesions

Angioma

Of 194 angiomas, cavernous and capillary, 52.6% were apparent at birth and 80.3% were noted during the first year of life. A majority of the affected patients (58.8%) were female. Although the dimensions were recorded in only 96 cases, most of these lesions (72.9%) were comparatively small, 0.1 cm to 1 cm in diameter. In 128 cases (66.0%) treatment consisted of irradiation (usually interstitial radiation involving implantation of radon seeds) or complete or partial excision with or without a skin graft. Radiation therapy was used in 60 (46.9%) of these 128 cases.

Mixed Tumor

Only two of the 24 mixed tumors were adherent to the skin; the others were located in the substance of the upper lip, unattached to skin or mucosa. Two thirds of the tumors became apparent when the patients were 30 to 59 years of age. Although mixed tumors can be painful, usually patients complained only of a lump in the lip. Treatment consisted of wide excision with primary closure of the wound or with local plastic repair. Four patients were lost to follow-up, but the others remained free of any evidence of recurrence at the time of follow-up study or of death, a matter of seven to 17 years after initial treatment.

Keratoacanthoma

The six patients having keratoacanthoma* ranged in age from 46 to 80 years, and the lesions varied from 0.3 to 1.5 cm in diameter. The average duration of these tumors was relatively short, about nine weeks, which is one clinical feature that distinguishes keratoacanthoma from basal-cell carcinoma. Four patients were treated by excision and primary closure

TABLE I

Classification of Tumor and Age and Sex Distribution of Patients

Type of lesion	Number	Per Cent	Male	Female	Average age, yr
Benign	272	38.7	127	145	53*
Neoplasms	231	85.0			
Angioma	194	71.3	80	114	
Mixed tumor	24	8.8	14	10	52
Keratoacanthoma	6	4.9	3	3	66

---

*See Test Your Word Score Page 933.

and one patient by excision and electrocoagulation of the base. Although one patient could not be traced, there were no recurrences in the other five cases after follow-up of five months to 11 years.

Miscellaneous Benign Tumors

These included three neurofibromas, one neurilemmoma,* one leiomyoma, one papilloma, and one calcifying epithelioma of Malherbe. Simple excision proved to be adequate therapy.

Hyperplastic Lesions

These lesions included only two instances of leukoplakia, in marked contrast to the frequency with which leukoplakia of the lower lip is encountered. All 24 lesions were excised and none recurred. The average age for the 17 male and seven female patients was 58 years.

Inflammatory Lesions

The 12 patients with inflammatory lesions averaged 55 years of age. Treatment consisted of antibiotic administration, excision, or incision and drainage, as indicated.

Cysts

The three mucous and two epidermoid cysts presented no diagnostic or therapeutic problems.

Malignant Lesions

Basal-Cell Carcinoma

Basal-cell epitheliomas comprised 73.3% of the malignant tumors and 82.6% of the carcinomas involving only the skin surface. There was an even sex distribution. The exact location was specified in 241 of the 315 lesions; 200 were located on the skin surface and 41 at the mucocutaneous junction where they were considered to have arisen from the skin. Tumor size was indicated in only 255 cases; it ranged from 0.1 cm to 5 cm.

The presenting signs and symptoms were those common to basal-cell carcinoma in any location, such as a cystic-appearing growth with or without ulceration, with scaling or crusting, and with evidence of rolled pearly borders.

Although excision with electrocoagulation of the base was employed in some cases, the most common method of treatment was excision—with primary closure of the wound in most instances, but with the use of a skin graft in a few. Irradiation was used in only four cases. There were 18 recurrences of which 16 could be controlled surgically; in the two remaining cases, the patients were lost to follow-up. The five-year survival rate was 86.0% (Table 2).

TABLE 2

Five-Year Survival Rates of Patients With Carcinoma of the Upper Lip

	Patients		Lived 5 or more years after treatment*	
Carcinoma	Total†	Traced	Number	Per cent
Squamous-cell				
Cutaneous	50	45	38	88.4
Mucocutaneous	9	9	7	77.8
Vermilion	17	15	11	73.3
Mucosal	6	6	2	33.3
Basal-cell	232	207	178	86.0
Total	314	282	236	83.7

*Based on traced patients; inquiry as of January 1, 1964.
†Includes only those patients treated in 1958 or earlier.

Squamous-Cell Carcinoma

Sixty of the 100 squamous-cell carcinomas of the upper lip were located on the skin surface, 11 on the mucocutaneous border, 18 on the vermilion portion of the lip, and seven on the mucosal surface. The locations of four lesions were not given. Of patients with this disease, 71.0% were male.

The most common presenting symptoms in cases of squamous-cell carcinoma of the upper lip were scaling, crusting, and ulceration; the most common signs were ulceration, crusting, keratotic change, thickening, and induration.

The problem of metastasis to cervical lymph nodes is much less serious in carcinoma of the upper lip than in that of the lower. Cervical lymph nodes were palpable on admission in seven of the 100 cases of squamous-cell carcinoma of the upper lip. Metastasis to regional lymph nodes occurred in only six cases. Although only the submaxillary group of lymph nodes was involved in five of these cases, distant metastasis did develop in the sixth case.

Except for three cases in which irradiation was employed, the squamous-cell epitheliomas in our series were treated by excision and primary closure or, in a few instances, by excision and electrocoagulation.

---

*See Test Your Word Score Page 933.

Local recurrence was a problem in 13.3% of carcinomas involving skin surface, in none of those of the mucocutaneous border, in 11.1% of those on the vermilion portion, and in 42.9% of those originating on the mucosal surface.

The five-year survival rate was 77.4% (Table 2).

Cylindroma

Patients with cylindroma of the upper lip ranged in age from 35 to 60 years, and the duration of the disease before they sought treatment at this clinic averaged 5.7 years. While these patients complained mainly of a lump or of thickening of the lip with some soreness, the only physical sign of any importance was an indurated nodule or mass within the substance of the lip.

Two of the four patients were treated by excision and electrocoagulation, one by electrocoagulation alone, and the fourth, who had a recurring cylindroma, by interstitial irradiation in the form of radon seeds. Two patients had metastasis, and one of these also showed evidence of local recurrence; however, despite local recurrence and regional and distant metastasis, the latter individual was living seven years after the initial treatment. The other patient had pulmonary metastasis and was lost to follow-up study. The two patients without metastasis were living 16 and 18 years after treatment of the primary lesion; they showed no signs of local recurrence or metastasis.

Malignant Melanoma

All three patients with malignant melanoma—two female, 63 and 34 years old, and one male, 60 years old—had treatment prior to their registration at this clinic. Treatment here consisted of excision and electrocoagulation in one case and excision of scar tissue (no evidence of residual tumor) in the second. No local recurrence or metastasis was ever found in these cases after seven and five years, respectively. The third patient received no treatment and was subsequently lost to follow-up.

Other Malignant Tumors

The remaining eight tumors included one adenocarcinoma (arising on the midcutaneous surface of the upper lip of an 81-year-old woman), three lymphomas, one leukemic infiltrate (in a four-year-old boy), and three metastatic carcinomas. In regard to the last three tumors, the primary lesions were located in the kidney, rectosigmoid colon, and lung, respectively.

Comment

Benign Lesions

Although angiomas of the upper lip can make their appearance at any age, 80.3% of such lesions in our study were noted during the first year of life. These findings correspond with those reported by other authors concerning hemangiomas in general.[1,2] Since there is no uniformity in the care of patients with angiomas at various medical centers, the treatment of these lesions presents a complex problem. However, since many angiomas undergo spontaneous regression, it probably is preferable in most cases *to defer any treatment for the first two years of life* or until one is certain that there is little likelihood that the lesion will disappear. Small angiomas should usually be removed surgically, especially if they can be excised without distorting the lip. Large ones which do not regress are often best treated initially by means of interstitial irradiation in the form of radon seeds; this practically always produces some shrinkage. Subsequently, plastic surgical techniques can be employed to improve the appearance and contour of the lip.

Aside from angiomas, mixed tumors are the most common benign tumors to involve the upper lip. Excluding the angiomas, 24 (64.8%) of the 37 benign tumors in our series were mixed tumors. Chaudhry and co-workers[3] found that 61% of all intra-oral minor salivary gland tumors were benign, that 39% were malignant, and that mixed tumors comprised 56% of all the benign and malignant neoplasms. Except for the palate, they found the upper lip to be the most common location. Among the nodules located in the substance of the upper lip, mixed tumors are more frequently encountered than any other type of benign growth. The likelihood of a nodule in the substance of the upper lip being either a mixed tumor or a cylindroma is 72.4%; consequently, such nodules should not be disregarded. Because a mixed tumor is usually well encapsulated, it can be satisfactorily treated by simple excision. Should the overlying skin or mucosa be adherent, the attached epithelium should be removed along with the tumor.[3]

The diagnosis of keratoacanthoma is based on the history, the appearance of the lesion, and the microscopic picture. Often confused with basal-cell carcinoma, keratoacanthoma cannot be diagnosed with complete certainty until a specimen is examined microscopically. Treatment of this type of benign lesion involves nothing more than simple excision.

Malignant Lesions

About 2.1% of cutaneous epitheliomas occur on the upper lip; of these, nearly 80% are basal-cell carcinomas; the rest are squamous-cell carcinomas.[4,5] In the present study, 381 malignant lesions involved the cutaneous surface of the upper lip, of which 315 (82.7%) were basal-cell carcinomas and 60 (15.8%) squamous-cell. Male and female patients were equally affected by basal-cell carcinomas of the upper lip, while 73.3% of the squamous-cell carcinomas of the skin occurred in men. The average ages of patients having basal and squamous-cell carcinomas in our series (Table 1) were similar to those reported by other authors.[4,5]

Squamous-cell carcinoma of the vermilion portion of the upper lip is relatively rare. During 20 years only 18 cases of squamous-cell carcinoma of this part of the upper lip were found, as compared to 1,802 cases of the lower lip—a ratio of 100 to one. Of the squamous epitheliomas on the vermilion part of the upper lip, 77.8% affected patients from 50 to 79 years of age, which is similar to the age-related incidence for such involvement for carcinoma of the lower lip. Only 1% to 3% of such carcinomas of the lower lip affect female patients.[6-8]

Metastasis of squamous-cell carcinoma involving the skin of the upper lip in this study occurred in five of 60 cases (8.34%)—noted on admission in one case and during follow-up examinations an average of one year after treatment in four cases. In squamous-cell carcinoma of the vermilion portion, regional lymph-node metastasis occurred in one of 18 cases (5.56%). Newell[9] observed this complication in 6.3% of his cases. Other authors have reported a higher incidence.

Treatment of primary and metastatic basal-cell carcinoma and squamous-cell carcinoma of the upper lip at this institution is primarily surgical. However, radical neck dissection is usually deferred until there is clinical evidence of metastasis.

Cylindroma of the upper lip is rare. In reviewing the literature from 1927 to 1960, Chaudhry and co-workers[3] found 11 malignant salivary gland tumors of the upper lip, of which six were cylindromas. We found four such lesions. Treatment should consist of wide surgical excision, alone or with irradiation;[3] but, regardless of the method of therapy, recurrences are common. Because of their slow growth, recurrence or metastasis may not become evident for five to 10 years or even longer.[3]

Summary

Of 702 tumors of the upper lip, 38.7% were benign and 61.3% malignant. Of the benign lesions, angiomas and mixed tumors were the most common, comprising 71.3% and 8.83%, respectively, of the total. Of the malignant lesions, basal-cell carcinoma was encountered much more frequently (73.3%) than was squamous-cell carcinoma (23.3%). The latter lesions were distributed as follows: skin 60%, mucocutaneous border 11%, vermilion surface 18%, and mucosa 7%.

Squamous-cell carcinoma of the vermilion portion of the upper lip is rare compared to the frequency with which such lesions are encountered on the lower lip. For each 100 squamous-cell epitheliomas of the lower lip, there was one of the upper lip. The incidence in female patients of carcinoma of the upper lip (22.2%) was higher than that for carcinoma of the lower lip (1% to 3%). The frequency of metastasis and the rate of growth were not found to be any different for squamous-cell carcinoma of the upper lip than for that of the lower lip. However, squamous-cell carcinoma of the mucosa on the under surface of the upper lip had a high incidence of local recurrence.

Of 34 tumors situated in the substance of the upper lip, 22 were mixed tumors and four were cylindromas.

When some men discharge an obligation, you can hear the report for miles around.—Mark Twain

Old Hospitals

Fort Crawford Military Hospital (restored)

First Medical Research in the Upper Midwest

The Fort Crawford Military Hospital at Prairie du Chien, Wisconsin, was under construction during the period August, 1829, to March, 1831, when the post surgeon, Dr. William Beaumont, was conducting most of his classic experiments on the physiology of digestion. The Fort Crawford experiments, fifty-six in number, were probably conducted in the old log hospital which this building replaced. Although stationed at a wilderness outpost with only the most rudimentary facilities, Beaumont used his knowledge of the world literature on gastric physiology and the gastric fistula of his assistant, Alexis St. Martin, to make one of America's greatest contributions to basic medical science.

Fort Crawford Military Hospital

The first eight experiments at Fort Crawford were on gastric temperature and the influence of changes in environmental temperature. The next fifteen were on the accumulation of gastric juice during fasting and under the influence of hunger. Twenty-three experiments compared natural digestion with the *in vitro* effects of gastric juice. The final ten experiments at Fort Crawford were an unsatisfactory series on the effects of bile and pancreatic juice. Beaumont's book, "Experiments and Observations on the Gastric Juice, and the Physiology of Digestion," was published in 1833 at Plattsburgh, New York.

The trouble with women...

frequently
is men

FLAGYL®
brand of metronidazole

Cures Trichomonal Infection in Both

Although *Trichomonas vaginalis* infection occurs in only 5 to 10 per cent* of men, careful diagnosis will demonstrate the condition in about half of all husbands of infected women. Nine investigators* reported an average incidence of 50.8 per cent in exposed consorts.

Many clinicians have achieved a high degree of success in treating trichomonal vaginitis only after they have recognized the importance of sexual partners in perpetuating the infection. Crowley* has asserted, "it was not until we acted on this key premise that we were able to obtain positive and lasting results in our management of recurrent vaginal trichomoniasis."

Simple ten-day oral treatment with Flagyl virtually assures elimination of established trichomonal infection in men. In twenty-two of twenty-seven studies* data on the results of treating male patients revealed that all men treated with Flagyl were cured.

Indications: Flagyl is indicated in the treatment of trichomoniasis in both men and women.

Contraindications: Pregnancy; disease of the central nervous system; evidence or history of blood dyscrasia.

Precaution: Complete blood cell counts should be made before, during and after therapy, especially if a second course is necessary.

Side Effects: Infrequent and minor side effects include nausea, metallic taste and furry tongue. Gastrointestinal disturbances, flushing and headache sometimes occur, especially with concomitant ingestion of alcohol. The taste of alcoholic beverages may be altered. Other effects, all reported in an incidence of less than 1 per cent, are diarrhea, dizziness, vaginal dryness and burning, dry mouth, rash, urticaria, gastritis, drowsiness, insomnia, pruritus, sore tongue, darkened urine, anorexia, vomiting, epigastric distress, dysuria, depression, vertigo, incoordination, ataxia, abdominal cramping, constipation, stomatitis, numbness or paresthesia of an extremity, joint pains, confusion, irritability, weakness, cystitis, pelvic pressure, dyspareunia, fever, polyuria, incontinence, decreased libido, nasal congestion, proctitis and pyuria. Elimination of trichomonads may aggravate candidiasis.

Dosage and Administration: *In women:* one 250-mg. oral tablet three times daily for ten days. A vaginal insert of 500 mg. is available for local therapy when desired. When used, one vaginal insert should be placed high in the vaginal vault each day for ten days; concurrently two oral tablets should be taken daily.

In men: When trichomonads are demonstrated, one 250-mg. oral tablet twice daily for ten days in conjunction with treatment of his female partner.

Dosage Forms: Oral tablets–250 mg.
Vaginal inserts–500 mg.

Research in the Service of Medicine

...now fast relief of hay fever symptoms with

NTz®
Nasal Spray

When pollens fly, just one or two squirts of NTz in each nostril, followed in a few minutes by a second spraying, shrink swollen nasal passages almost on contact. And breathing comfort follows. The antihistamine component of NTz helps combat the allergic reaction and lessen rhinorrhea, sneezing and itching; its antiseptic wetting agent promotes rapid spread of components.

NTz Nasal Spray affords the well-known benefits of Neo-Synephrine® in a carefully balanced formula which includes:

NTz
nasal spray
antihistaminic decongestant
Winthrop

Winthrop

Neo-Synephrine® (brand of phenylephrine) HCl, 0.5% (adult strength), decongestant
Thenfadil® (brand of thenyldiamine) HCl, 0.1%, antihistamine
Zephiran® (brand of benzalkonium as chloride, refined) Cl, 1:5000, antiseptic wetting agent

Treatments with NTz should be repeated every three or four hours as needed. NTz is for temporary relief of nasal symptoms and overdosage should be avoided. Available in squeeze bottles of 20 ml. and 1 oz. bottles with dropper.

Subtalar Inflammatory Response to Stress

THE CIVILIAN PRACTICE of Orthopedic Surgery includes many patients with low back pain. The symptoms are definite and distressing, but often the physical findings are vague. Treatment is usually conservative, with rest being the keynote. Eventually most of these patients become asymptomatic and are able to return to work, although recovery is sometimes slow.

An interesting parallel is found in military practice. We see an enormous number of young men with painful feet. In the great majority there is a paucity of physical findings. Treatment is usually non-surgical and based on rest. The small minority who fail to respond are eventually discharged from the service.

To be sure, each patient must be carefully and individually evaluated, and generalizations are dangerous. But no one would deny that the possibility of secondary gain is often a factor in persisting complaints. Civilian patients involved in injuries covered by Workmen's Compensation or enmeshed in personal injury litigation may either subconsciously or overtly prolong rehabilitation. Similarly in military life, which for some is neither agreeable nor attractive, a well-placed symptom can result in at least temporary improvement of the environment. A 20-year-old draftee who has done nothing more vigorous than week-end bowling or carrying a sign in a campus demonstration might be expected to have symptoms of foot strain after a ten-mile hike on a hot asphalt road in combat boots with full field gear. Add to his sore feet the prospect of tomorrow's hike, grim at best, and you end up with a man in the dispensary. A day or two of rest and a few aspirin cure 90% of these people.

The patients with persistent pain are eventually more thoroughly evaluated, and orthopedic consultation is obtained. In the majority of these, significant physical findings are absent, x-rays unremarkable, and laboratory tests unrevealing. Rarely are such entities as tarsal coalition, stress fracture, arthritis, infection or tumor found. Therefore most of these cases are diagnosed as foot strain and the treatment remains conservative. Gradually they improve and rarely is complete rehabilitation impossible.

Chambers and Preator* selected patients with symptoms and signs of subtalar inflammation for steroid injection. As an initial and primary method of treatment this approach warrants some discussion. We have all seen individuals involved in sedentary activities for years who develop a painful joint after unusual exertion: the father out for little league football practice, the middle-aged matron after her first jogging, the bank vice-president after the three-legged race at the annual picnic. They come limping into the office with a painful swollen knee, a sore hip limited in internal rotation, or an effused and warm elbow. Treatment for these cases of traumatic synovitis is reassurance, analgesics and rest. Response to this

judicious hands-off policy is prompt and gratifying.

Only cases which prove intractable to an adequate period of conservative management are considered for injection therapy. Parenteral steroids and intra-articular injections should seldom be considered for initial therapy in a synovitis due to stress. Violation of a joint with a needle and medication can be associated with complications and should be reserved for patients unresponsive to simple measures. Chambers and Preator obtained excellent results in 19 out of 20 airmen treated by injection; one wonders how a randomly-selected control group treated by rest would have fared.

Significance of Late-Developing Reaction in Allergy Skin Testing

THE DIAGNOSIS of a sensitivity to a specific allergen should correlate with the patient's history and symptoms when exposed to the suspected allergen. Skin testing with allergens continues to be a major diagnostic aid in the diagnosis of allergy. All allergists recognize the limitations of skin testing as presently employed. Their eagerness and enthusiasm for additional methods of detection are ever present.

Similar clinical entities involving the same shock organ, i.e., lungs, nose, skin, are repeatedly observed in patients—with one major difference, however. Some patients present positive skin tests of the immediate type, while others are totally non-reactive. This latter group continues to baffle the physician in the diagnosis and management of allergic disease. At present immunological mechanisms have not been implicated. The recent beta adrenergic theory of atopic abnormality by Szentivanyi[1] offers a plausible explanation for this group of non-reactors.

The interest of Doctors Max Michels and Robert Smith,* in bringing to our attention the presence of these late-developing skin reactions, will surely stimulate further interest. The correlation of these skin reactions with the patient's history, and with symptoms and eosinophilia after nasal challenge is suggestive but not conclusive. The authors' careful discussion in distinguishing these late-developing skin reactions from delayed hypersensitivity should help avoid confusion. To date, their clinical significance remains unclear. Confirmatory evidence in both the basic and the clinical laboratory is needed.

The Course of the Facial Nerve

THE ANATOMY of the facial nerve is of particular interest and importance.* When facial palsy is present, knowledge of this anatomy permits accurate localization of the pathology. As various portions of the nerve tend to be involved by different types of pathology, localization assists in narrowing the field of diagnostic possibilities and points to further diagnostic steps which might be helpful.

In evaluating facial palsy, the extent of the muscles involved must be determined. Central pathology, proximal to the facial nerve nuclei in the brainstem, results in impairment of the lower face only, sparing the muscles of the eyelids and forehead. Finding all portions of the facial musculature involved (though not necessarily to a uniform extent), if associated with disturbances of the trigeminal nerve, long tracts, or cerebellum, implies pathology at or adjacent to the brainstem. Acoustic neurinoma at the cerebellopontine angle, for example, may produce these findings.

Hearing disturbances often accompany facial palsy. Determination of the type of hearing loss allows further localization. The basic differentiation of sensorineural or conductive loss, as may be done with a tuning fork, may point to involvement either proximal or distal to the geniculate ganglion. Associated eighth nerve lesions involving the segment from the brainstem up to the cochlea often result in specific audiometric abnormalities (markedly impaired understanding of speech, pathological adaption to sound, etc.). Involvement of the cochlea itself results in sound recruitment. Involvement at or adjacent to the middle ear, the "tympanic" (horizontal) segment, is often associated with conductive hearing loss, most commonly by middle-ear disease or by trauma. In these instances otoscopy and the history are of prime importance.

Involvement of the "mastoid portion" (vertical segment) of the facial nerve is most commonly by Bell's Palsy. This is probably basically a problem of localized ischemia and is associated with no other cranial nerve abnormalities. Beyond the stylomastoid foramen, involvement may be of the main trunk or of branches and thus cause regional muscle impairment. In these instances the etiology is most commonly trauma or tumor.

Further localization may be possible based on (1) the exit of the greater petrosal nerve from the geniculate ganglion (employing tear tests), (2) the exit of the nerve to the stapedius muscle (resulting in impaired stapedius muscle function and thus impaired damping of the stapes' excursions, with increased perception of and distress with exposure to loud sounds) and (3) the entrance of the chorda tympani nerve (with accompanying taste and salivation disturbances); but evaluation of these may be more difficult and less reliable.

Thus a knowledge of the course and relationships of the facial nerve allows the localization of its pathologic involvement and facilitates appropriate diagnostic steps and conclusions.

Time

One morning, Andrew Carnegie interviewed two boys for a position. He placed a package in front of each, and told them to start unwrapping. One boy carefully untied the string and placed it in a drawer. The other reached for a pair of scissors, snipped the twine and tossed it into the wastebasket. Carnegie then asked the boys to wait outside.

"Shall I hire the boy who saved the string?" asked his secretary.

"No, I want the other boy," said the steel magnate. "The days of string-saving are over. We're time-savers now."

—Read.

"If a free society
cannot help
the many
who are poor,
it cannot save
the few
who are rich."

You May Be Right

Leg Cramps*

The article by Thurn entitled "Treatment of Leg Cramps of Pregnancy with Vitamin B6"*, and the accompanying editorial note in the February issue of *Minnesota Medicine* call for further comment.

The suggestion that an individual in general practice cannot do scientific work without a clinical laboratory is false. Furthermore, the idea of tryptophane loading tests to determine vitamin B6 deficiency, although interesting, is not of importance in substantiating the hypothesis that this agent is of value in the treatment of leg cramps.

Those who watch tooth-paste commercials on television know that the proper experimental design for such a study is a double-blind one. This could easily be done in a general practice setting. A statistically valid difference between drug and placebo groups would provide evidence in support of the hypothesis. An insignificant difference would suggest that the relief of pain was due to psychological or other factors.

The suggestion that other physicians use this treatment in order to provide a larger clinical experience is a poor one since, without a properly controlled study, no meaningful results can be obtained, no matter how many patients are treated.

This lack of proper controls in clinical studies has resulted in many unsettled questions in medicine: for example, the value of long-term anticoagulants in the prevention of recurrence of myocardial infarction.

David A. Berman, M.D.
Minneapolis, Minnesota

---

*Thurn, R. J.: Treatment of Leg Cramps of Pregnancy with Vitamin B6. Minnesota Med 52:267, 1969.

Acute Abdominal Emergency*

As the New England Journal of Medicine pointed out recently,[1] Clinical Path Conferences are stimulating to those of us who care for patients even though they may not be as glamorous as presentations in the exciting frontiers of immunology, chromosomal abnormalities, and molecular biology. A case in point is the report of an acute abdominal emergency after gastrectomy beautifully described by Strom in MINNESOTA MEDICINE.* Since a classical education is now so rare we may see more "crur*ae*"† just as we hear a lot about "diverticu*li*."† In reflecting on this case one feels that the recent suggestion[2] about the advisability of exploration with the diagnosis of pancreatitis should be seriously considered. Laparotomy has become remarkably innocuous; the main complication is aspiration pneumonia. If this can be avoided it seems better to make a small incision rather than depend upon blind needle paracentesis which may give intra-luminal bowel content rather than peritoneal fluid.

A recent case of afferent loop obstruction due to volvulus at the gastroenterostomy was seen in our hospital nine years after gastrectomy; the 9-cm. wide duodenum in the right upper quadrant was pierced by the paracentesis

and the fluid was reported as bile and containing too much amylase to measure accurately.

Another of our patients diagnosed as having pancreatitis who came in drunk with a positive Cullen's[†] and Grey-Turner[†] sign developed pleural effusion after two or three days which on tapping revealed bile.

Laparotomy showed a transected common bile duct as well as disruption of the gastroduodenal artery due to unknown blunt injury. He, like the patient reported in the Clinical Path Conference, died. Thal and Perry[3] maintain that patients who developed signs of pancreatitis after having had gastrectomy should be promptly operated upon.

In all, this was a very stimulating and topical case. Those who continue to prefer gastrectomy to vagotomy and pyloroplasty, in the management of the complications of duodenal ulcer, have to answer for the higher immediate mortality and the severity of those complications, such as problems with the afferent loop or complications of marginal ulceration which occasionally develop even many years later.

The Editor's Soliloquy

Litigation Disease

To listen to court testimony regarding an accident, the average undiscriminating person might well conclude that nearly any disease or disability can potentially result from an accident. Plaintiffs' attorneys have astutely garnered from their clients' experiences an exhaustive list of ailments and complaints from A to Zed—as possible if not probable sequels of an accident.

"After all, there is nothing to lose!" Why not incriminate an accident for that headache, that crick in the neck, that twinge in the back, that you-name-it, that mysteriously appears sometime *after* an accident in the victim who was "never subject to previous headaches, cricks, or twinges!"

Unfortunately, "qualified and expert" testimony has "established" that a remote three-to-four-year-old non-organic strain, without bruise, fracture, laceration or muscle rupture, has "caused" obvious new disease or "contributed" to pre-existing disease.

The fallacy: *post hoc; ergo propter hoc** dies a hard death; it has persistently plagued logicians down the centuries and is still accepted by the untutored and exploited by the unscrupulous. Consecutiveness *per se* does not imply causality and should never constitute a basis for sound medical doctrine.

Neither incidents nor accidents cause disease. If an injury has been sustained, the victim will suffer the effects of that injury immediately; on the other hand, any injury which does not cause immediate distress is indeed a minor one and represents nothing more serious than a non-organic strain, comparable to what any athlete might experience after strenuous activity. Such discomfort is physiologic, not organic.

Even if the injury is severe enough to cause organic damage (a fracture, muscle rupture, ligament tear, skin laceration), these damages heal in a more or less scheduled period of time. When healing is complete most of the sequelae of that injury are terminated. The chapter on that incident is closed!

Litigation disease has its obvious etiology: the history relates an incident, usually referred to as an injury, and subjective symptoms referable to almost any extant set of symptoms or disease; the physical findings are irrelevant, the treatment is immaterial, and the prognosis is contingent upon the outcome of the pending lawsuit or its settlement.

Litigation disease is not catalogued in medical annals; but it does exist.

MINNESOTA MEDICINE

HONOR AWARD

Minnesota Medicine Medical Writing Awards, 1969

It is with pleasure that the Board of Editors announces the winners of the eighth annual Minnesota Medicine Medical Writing Awards chosen from articles published in Minnesota Medicine during the year of 1968.

First place plaques were awarded by Dr. Carl Rice during the annual meeting of the Minnesota State Medical Association in Minneapolis at the New Members, County Officers and Delegates Dinner to Donlin M. Long, M.D.; Shelley N. Chou, M.D. and Lyle A. French, M.D., for their article "Evaluation and Treatment of Hydrocephalus"; and to Yoshio Sako, M.D. and Martin L. Beard for their article "Coarctation of the Aorta in Veterans", which appeared in the June, 1968, issue of Minnesota Medicine.

Certificates for excellence in medical writing were awarded to the authors whose articles were felt to be particularly outstanding by the Board of Editors. These authors are listed on page 939.

Laboratory Letter

The trouble with urinary steroid tests is that so many variables, other than endocrine disorders, influence results. Among these are: completeness of urine collection; stress; age and sex; varying excretion rate of steroids during the day; and interfering substances such as drugs.

In theory at least, you can control most of these variables. You place the patient in the hospital, instruct nurses to collect all urine for 24 hours, and hope the hospital atmosphere doesn't cause too much stress. The 24-hour collection period helps assure you of an adequate specimen and gets you around the diurnal variation problem: 17-ketosteroid values peak in the morning, vary during the day, and dip during sleep. Besides this normal shifting, emotions and physical activity can change results. Still, in ambulatory patients and in some hospital patients, you can't be sure of basal conditions.

Age and sex pose less of a problem. Once you get your results, you refer to normal ranges for age and sex (Table 1), and you keep in mind that in women, 17-ketosteroids roughly measure androgenic activity. You know that in women the adrenals are the source of almost all 17-ketosteroids, while in men the adrenals account for only two thirds. The testes supply the other third. And you appreciate that in both sexes 17-ketogenic steroids are a better measure of adrenal activity than 17-ketosteroids.

TABLE I

Normal Values For Urinary Steroids

	Age-yrs.	Men	Women
17-Ketosteroids	2-5	Less than 2 mg./24 hrs.	Less than 2 mg./24 hrs.
	5-10	3-6 mg./24 hrs.	3-6 mg./24 hrs.
	10-15	6-15 mg./24 hrs.	5-11 mg./24 hrs.
	15-60	10-20 mg./24 hrs.	5-15 mg./24 hrs.
	60-90	5-20 mg./24 hrs.	3-13 mg./24 hrs.
17-Ketogenic Steroids	Under 1 yr	Less than 1.0 mg/24 hr.	Less than 1.0 mg/24 hrs.
	2-5	1-5 mg/24 hrs.	1-5 mg/24 hrs.
	5-10	2-9 mg/24 hrs.	2-9 mg/24 hrs.
	20-50	11-22 mg/24 hrs.	7-18 mg/24 hrs.
	Over 50	4-14 mg/24 hrs.	2-10 mg/24 hrs.

Drugs? Well, you try to keep them from interfering with the tests by stopping all medications 48 hours before the urine collection. But, human nature being what it is, some patients forget and others don't always follow instructions to the letter. As a consequence, you may get puzzling drug-induced results. If this should happen, you may want to consult this table.

TABLE 2

Drug	17-Ketosteroids	17-Ketogenic steroids
1. Meprobamate, Triacetyloeandomycine, Spirolactone, Phenaglycodal (Ultran), Penicillin, and Nalidixic Acid (NegGram)	increases	increases
2. Chlordizepoxide hydrochloride (Librium), and Etryptamine acetate (Monase)	decreases	increases
3. Chlorpromazine (Thorazine)	increases	decreases
4. Hydroxysine (Atarax)	no effect	increases
5. Ethinmamate (Valmid)	increases	no effect
6. Reserpine	decreases	decreases

WHAT'S
SO WEAK
ABOUT
THE WEAKER
SEX?

OFTEN... HER LOWER G. I. TRACT

Psycho-abdominal Distress: Frequently Female

Women aged 15 to 45 appear to be more prone than men to bloating, cramping pain of stress-related intestinal disturbances such as irritable or spastic colon.[1,2]

Frequently Recurrent

In the experience of many physicians, women are more likely to reappear time after time with repeated complaints of lower G.I. distress.

Requiring Definitive Therapy

Often needed is therapy adequate to control both the somatic and the emotional components of psycho-abdominal complaints.

Definitive Dual Therapy

'Milpath' contains a proven synthetic anticholinergic useful for relieving hypermotility, spasm, and hypersecretion of the gastrointestinal tract.

In addition, 'Milpath' provides a time-tested tranquilizer for mild but effective anti-anxiety action.

With Flexible Dosage

- 'Milpath'-400 (meprobamate 400 mg. + tridihexethyl chloride 25 mg.) Usual adult dose: 1 tablet *t.i.d.* and 2 at bedtime.
- **When less tranquilization is required: 'Milpath'-200 (meprobamate 200 mg. + tridihexethyl chloride 25 mg.)**

Wallace Pharmaceuticals/Cranbury, N. J. 08512

gently but firmly

MILPATH®

(meprobamate + tridihexethyl chloride)

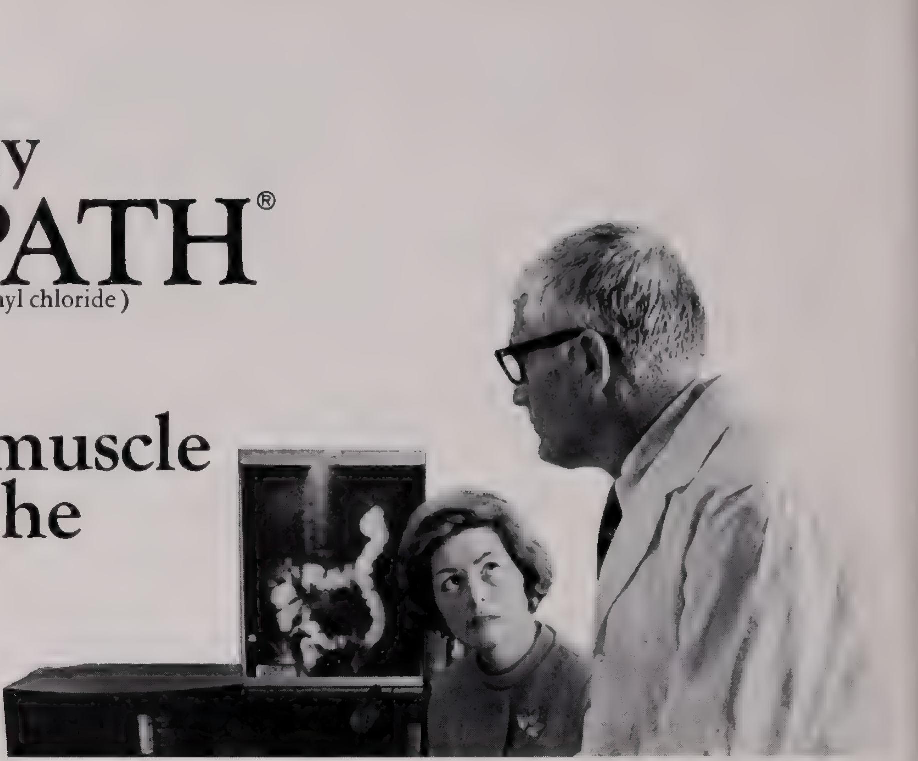
relaxes smooth muscle and psyche

Please see the following page for brief summary of prescribing information.

Gently but firmly MILPATH®

(meprobamate + tridihexethyl chloride)

Relaxes smooth muscle and psyche



Usual Adult Dosage

One 'Milpath'-400 tablet, three times a day at mealtimes, and two at bedtime. For greater anticholinergic effect, two 'Milpath'-200 tablets, three times a day at mealtimes and two at bedtime. Doses of meprobamate above 2400 mg. daily not recommended.

Indications

Useful in organic and functional disorders with hypersecretion and hypermotility of G.I. tract, especially when accompanied by anxiety, neurosis, or tension states. Should be used as an adjunct to all other therapeutic measures.

Contraindications

Tridihexethyl chloride: Urinary bladder-neck obstructions, e.g., prostatic obstruction due to hypertrophy; pyloric obstructions because of reduced motility and tonus: organic cardiospasm (megaesophagus); glaucoma; possibly in stenosing gastric or duodenal ulcers with significant gastric retention.

Meprobamate: Previous allergic or idiosyncratic reactions to meprobamate.

Precautions

Tridihexethyl chloride: Use cautiously in elderly males (possible prostatic hypertrophy).

Meprobamate: Carefully supervise dose and amounts prescribed. Consider possible dependence or habituation (reported occasionally after excessive use), particularly in severe psychoneurotics, alcoholics, ex-addicts. Withdraw gradually (one or two weeks) after excessive dosage for weeks or months to avoid recurrence of pre-existing symptoms (e.g., anxiety, anorexia, insomnia) or withdrawal reactions (e.g., vomiting, ataxia, tremors, muscle twitching; rarely, epileptiform seizures, more likely in those with CNS damage or latent convulsive disorders). If drowsiness or visual disturbance occurs, reduce dose and advise against activity requiring alertness (driving, machinery operation). Effects of excess alcohol may be increased. Grand mal seizures possible in persons with both petit and grand mal. Prescribe cautiously in small amounts to patients with suicidal tendencies. Prescribe with caution to patients with known sensitivity to compounds of similar chemical structure, e.g., carisoprodol.

Side Effects

The following side effects of components may occur with 'Milpath'.

Tridihexethyl chloride: Severe effects rare on recommended dosage. Anticholinergic effects: dry mouth (fairly frequent at oral doses of 100 mg.), constipation or "bloated" feeling. Possible: tachycardia, dilation of pupils, increased ocular tension, weakness, nausea, vomiting, headache, drowsiness, urinary hesitancy or retention, dizziness.

Meprobamate: Drowsiness, sometimes with ataxia, usually controlled by decreasing dosage, occasionally with aid of central stimulants (e.g., amphetamine). Rarely, allergic or idiosyncratic reactions (usually after one to four doses); in mild form: itchy, urticarial or erythematous, maculopapular rash, generalized or confined to groin. Acute nonthrombocytopenic purpura with cutaneous petechiae, ecchymoses, peripheral edema and fever, transient leukopenia, and one fatal bullous dermatitis (after meprobamate and prednisolone) reported. More severe, very rare hypersensitivity: fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (one fatal), anuria, anaphylaxis, stomatitis and proctitis. Treat symptomatically (e.g., epinephrine, antihistamines, possibly hydrocortisone); stop and do not restart the drug. Isolated agranulocytosis, thrombocytopenic purpura, one fatal aplastic anemia reported, but only in presence of known toxic drugs, porphyric symptoms reported but relationship not established. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation reported by one observer. Fixed drug eruption with meprobamate and cross reaction to carisoprodol reported.

Suicidal attempts may produce drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse, and death. Excessive dosage has led rapidly to sleep, then reduction of vital signs to basal levels. Empty stomach, and if respiration becomes very shallow and slow, cautiously give CNS stimulants (e.g., caffeine, pentylenetetrazol, amphetamine); also pressor amines if indicated.

Supplied

In two strengths:

'Milpath'-400: Yellow, scored tablets.

'Milpath'-200: Yellow, coated tablets.

Before prescribing, consult package circular.

The Viewing Box

Severe Generalized Abdominal Pain

This 28-year-old lady was admitted with the complaint of sudden onset of severe generalized abdominal pain, worse in the left flank and radiating to both shoulders on lying down. This was accompanied by vomiting and faintness. Her last normal menstrual period was seven weeks prior to admission. Physical examination revealed a pale woman with blood pressure 90/60, pulse 140. Her abdomen was flaccid but tender. This tenderness was greatest in the L.L.Q. and hypogastric regions. Pelvic examination showed pain on motion of the cervix and fullness in the pouch of Douglas. The uterus was slightly enlarged. No adenexal mass was palpable. A supine film of the abdomen was made (Figure 1).

What is your diagnosis? (See next page.)

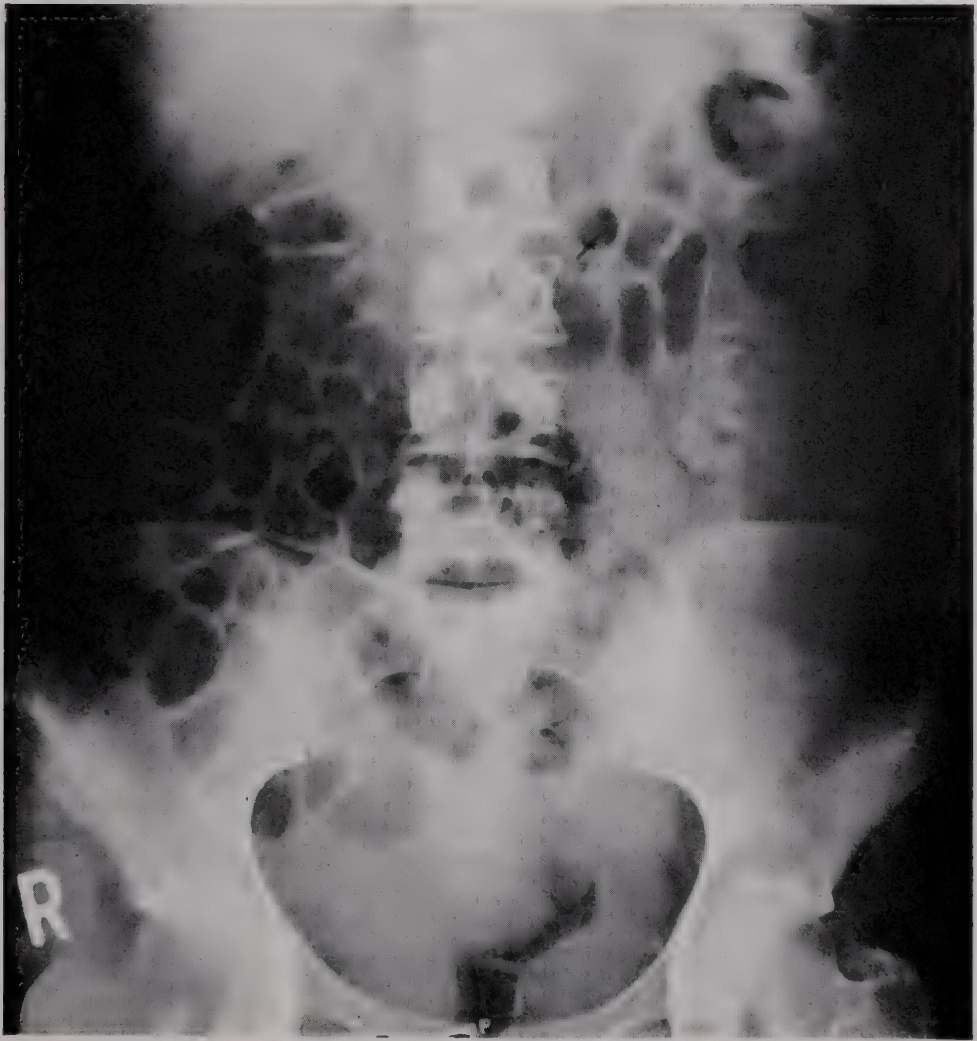

Figure 1

Diagnosis: Ruptured ectopic pregnancy with secondary hemotoperitoneum.

We are all acutely aware of the extreme importance of recognizing the presence or absence of intraperitoneal fluid or blood, whether caused by trauma or acute or chronic disease processes. There are several well recognized roentgenologic signs of free intraperitoneal fluid which will increase our diagnostic acumen in this area. These are the "dog's ears sign," "flank stripe" and obliteration of the hepatic angle (Figure 2).

These signs are best evaluated on supine films of the abdomen using a low kilovoltage technique. The first of these is the "dog's ears sign" of fluid in the pelvic recess. The pouch of Douglas and peritoneal recesses on each side of the rectum and bladder are the lowest portions of the peritoneal cavity and tend to fill with fluid first. This fluid extends superiorly above the bladder and resembles the projecting ears of a dog. As the amount of fluid increases, it

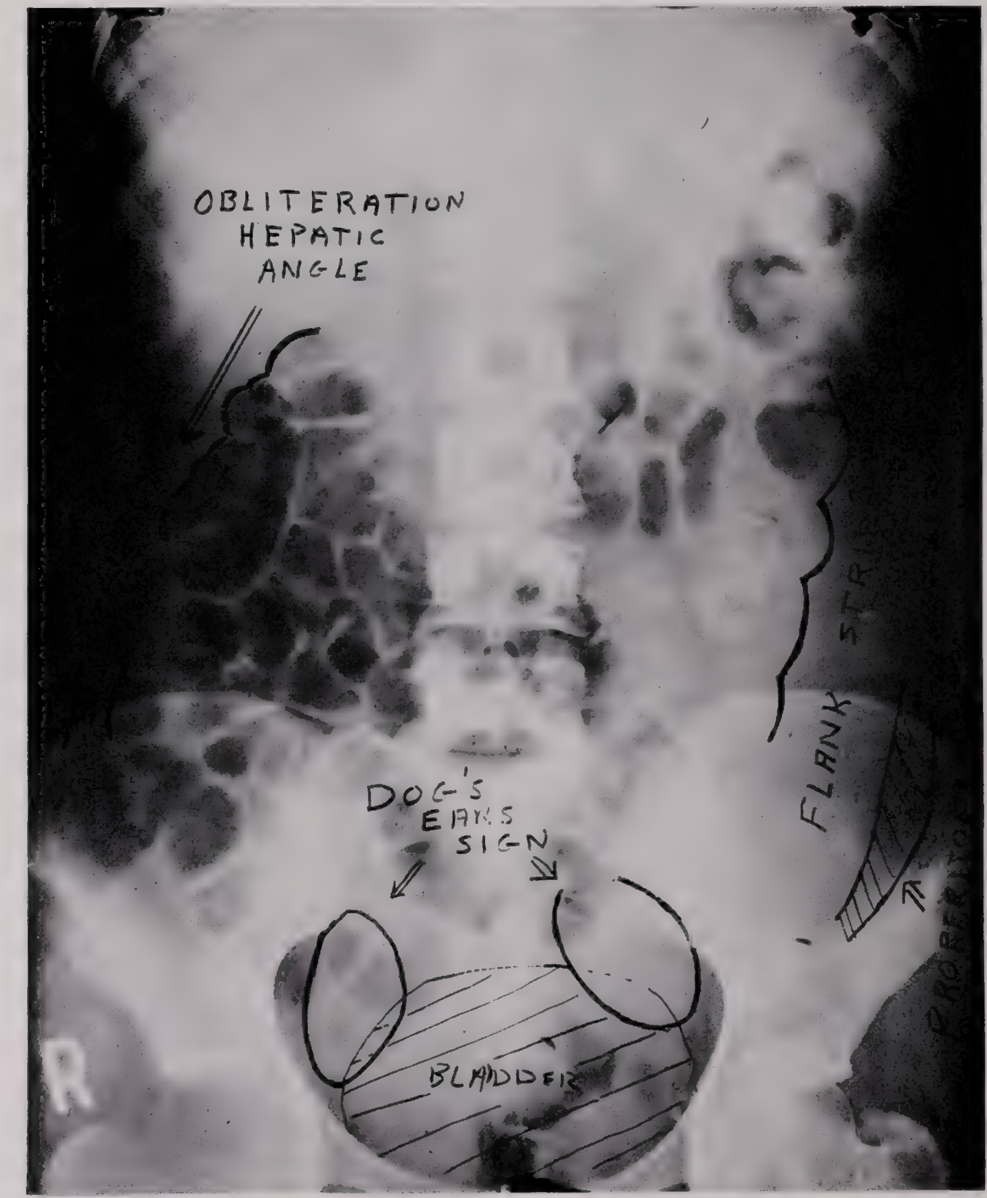

Figure 2

spills out into the flanks and causes flattening of the haustra and displacement of the colon medially away from the extraperitoneal or properitoneal fat line, giving us our second sign—the "flank stripe." One thousand cc. of free fluid should produce a definite stripe.[1] The properitoneal fat line is that lucent line seen on plain film which lies between the peritoneum and transverse abdominal muscle. The colon normally lies within 2 mm. of this line.

The last sign is the obliteration of the hepatic angle. The lower right lateral margin of the liver is normally clearly seen because of the large quantity of omental fat contiguous with the liver at this point. When fluid is sufficient to reach this area it insinuates itself between these structures, obliterating the hepatic angle.

Margulies[2] feels that both the flank stripe and the hepatic angle are excellent signs in assisting us in the evaluation of the presence or absence of free fluid and that many of the difficulties encountered can be avoided by studying the right flank in the region of the hepatic angle. It must be remembered that fluid-filled small bowel may occasionally interpose itself between the descending colon and properitoneal fat line, giving us a false flank strip on the left. The site of trauma, the site of acute disease process and the position of the patient after injury or onset of the disease process influence the location of free fluid.

The roentgenogram used in this article shows all three signs. At surgery the patient was found to have 1500 cc. of free blood.

Automation and Medicine

Since the practice of medicine is essentially the computation of statistical probabilities I think there is little doubt that if all relevant information were stored in one place and made available for computation the accuracy and hence the quality of medical care would be greatly improved. . . . The seasoned clinician enlarges his knowledge and improves his statistical calculations as he grows older . . . but most of his acquired information dies with him. The computer remains immortal.

This development will not encroach upon the time-honored duties and values of the physician . . . but he will be forced to think quantitatively about the information he obtains. This in itself will greatly increase the value of clinical data and will heighten the perceptions and analytical ability of the physician . . . his personality will remain a deciding factor in the therapeutic process, but he will no longer be forced to call upon his own memory for the complex assessment of the statistical probabilities of each diagnosis. . . . Fortified with the vast knowledge of a computer he will more fully develop his own potential as a physician and as a human being.*

Book Reviews

The true University of these days is a Collection of Books.—Carlyle

WATER AND ELECTROLYTE METABOLISM AND ACID-BASE BALANCE. By Edward Muntwyler, Ph.D. C. V. Mosby Company, St. Louis, 1968. Price: $5.85.

This paper-bound handbook has 143 pages of text, a useful set of 311 references and a reasonably usable index.

It is divided into three sections, the first covering water and electrolyte metabolism as a general foundation of the basic physiologic processes. This, as well as the second section covering the basic physiology of acid-base balance, make up an excellent review so that the physician can much better understand problems to be dealt with. A very helpful summary of the Brønsted-Lowry concept of the source of hydrogen ions and their disposition can be found on pages 59 to 65.

The third section on correction of fluid, electrolyte, and acid-base balance disturbances is primarily designed for the internist or those dealing with non-surgical problems. There is actually very little coverage of the rather wide variety of distorted conditions that the surgeon deals with, such as the translocation of fluids and electrolytes in massive infectious processes, the mixed metabolic and respiratory problems, and those of excessive drainages of various body secretions and excretions.

This booklet should be quite useful, therefore, as a review of the general subject of water and electrolyte metabolism and acid-base balance and chemistry of blood gases. For the practicing physician, this booklet is particularly pertinent. It should also be useful as an examination review.

J. H. Strickler, M.D.
Minneapolis, Minnesota

RADIOACTIVE NUCLIDES IN MEDICINE AND BIOLOGY. Volume II, Third Edition. Author—Solomon Silver. Publishers—Lea and Febiger.

The third edition of this book was timely because of the significant advances in nuclear medicine since the previous edition which was published in 1962. The present volume contains 539 pages which is over 200 pages more than in the second edition. The first half of the book deals with the thyroid gland so that it represents a complete monograph on this subject. There is more detail on the evaluation and treatment of thyroid than is probably needed for most nuclear medicine clinics and reflects the primary interests of the author.

This volume contains several chapters which were not present in the previous edition. These chapters relate to scanning, measurements of blood flow and renal function. Sufficient detail is included on these subjects to make them adequate for most readers who are involved in the practice of nuclear medicine.

No consideration is given in this book to the advances in nuclear instrumentation and recent developments in radiopharmaceuticals. It is assumed that these subjects will be covered in detail in the third edition of Volume I, which is yet to be published.

The list price of this book at $12.50 makes it very competitive with several other books on the market dealing with advances in nuclear medicine.

Merle K. Loken, M.D., Ph.D.
Minneapolis, Minnesota

SURGERY OF THE ADRENAL GLANDS. By Lawrence W. O'Neal, C. V. Mosby Company. Price: $19.50.

This book is intended primarily for use by surgeons and contains contributions by nine internists, surgeons, anesthesiologists, radiologists, endocrinologists and pediatricians, all from St. Louis, Missouri. Although the principal author, Lawrence W. O'Neal, states that "the sheer volume of available information and its complexity are somewhat intimidating to the clinician," this volume contains in 286 pages a wealth of well organized material which should be of great value to every surgeon and clinician interested in this field. After discussion of embryology and anatomy of the adrenal glands, the biosynthesis, metabolism, physiology and function of adrenal hormones are discussed in depth. There are chapters on the commonly-found tumors of the adrenal glands, an excellent outline on sympathetic tumors and, in a different chapter, on pheochromocytoma, Primary aldosteronism, Cushing's syndrome, as well as virilizing and feminizing states, are treated in different chapters. A chapter devoted to adrenalectomy for carcinoma of the breast also contains abundant information on other endocrine ablative surgery as well as on chemotherapy. The chapter on roentgenology of the adrenal glands is unique and superb. Here one finds excellent film reproductions, for example of adrenal arteriograms, ACTH-producing lung cancers, or dental films showing the loss of lamina dura in Cushing's disease.

I wish the author had included a review of the recent history of discoveries in the field of adrenal surgery and physiology, and also an opinion concerning adrenalectomy for hypertension of undetermined origin, which is in my opinion still an unsettled problem.

Minneapolis, Minnesota

Fracture Conference

Fracture of the Os Calcis*

Dr. Edward D. Henderson:† We have an interesting problem to present this morning.

Dr. Richard T. Chiroff:‡ A 56-year-old white housewife fell off a ladder, a distance of approximately eight feet. After the fall, she complained of pain in the left foot, particularly in the heel, and was unable to bear weight on it. She was brought to the hospital where examination revealed swelling and ecchymosis over the entire left foot below the ankle. The neurovascular status of the distal portion of the foot was normal. She complained of some low back pain as well, but the neurologic examination revealed nothing abnormal. Roentgenograms of the lumbosacral part of the spinal column were normal.

Dr. Henderson: Dr. Boyce, what kind of a fracture is this?

Dr. Daniel Boyce:# It is a fracture through the calcaneus, and I think it involves the subastragalar joint (Figure 1).

Dr. George Simons:‡ This is certainly a comminuted fracture of the os calcis.

---

*Fracture conference held June 24, 1968.

†Consultant in Orthopedic Surgery, Mayo Clinic and Associate Professor of Clinical Orthopedic Surgery, Mayo Graduate School of Medicine, University of Minnesota, Rochester.

‡Resident in Orthopedic Surgery, Mayo Graduate School of Medicine, University of Minnesota, Rochester.

#Associate Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

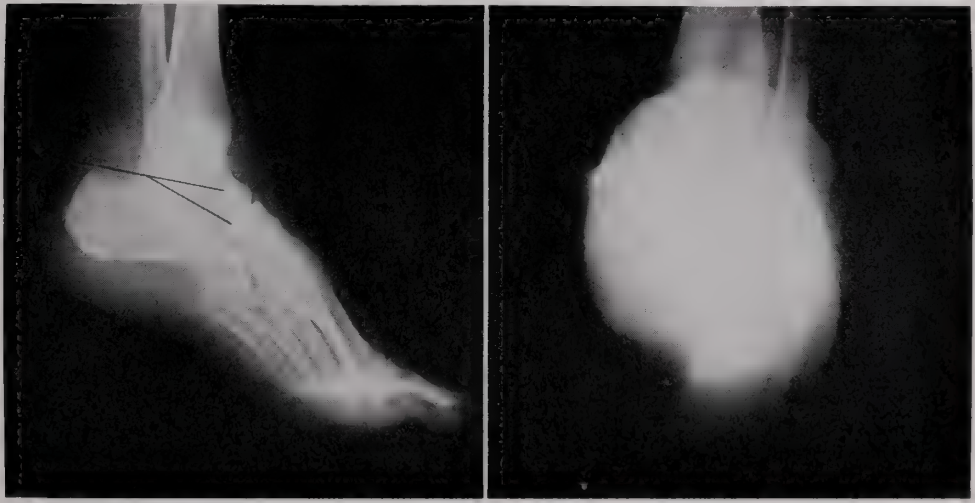

Fig. 1—At admission. (Left) Lateral view of left foot, showing loss of tuber joint angle (20 degrees) and marked comminution of fractured os calcis with involvement of subtalar joint. (Right) Tangential view of fractured left os calcis, showing lateral "spread" of bone and more or less intact medial cortex with single fracture line.

Dr. Henderson: How would you tell whether it went into the subtalar joint?

Dr. Simons: The right tuber joint angle appears somewhat reduced. I would say it is probably five or 10 degrees less than it should be. Also, one might take other films to show the fracture better.

Dr. Henderson: This is a type 6 Watson-Jones fracture—a comminuted fracture through the entire body of the os calcis with loss of tuber angle. These are the two aspects of fractures of the os calcis that make them difficult to treat. There are many methods of treatment, all the way from putting on a well-padded cast and allowing the patient to walk on it, to various types of open reduction with or without bone grafting, to triple arthrodesis, to primary subastragalar arthrodesis. There are also many methods of closed reduction with or without insertion of Steinmann pins. The reason I bring this up is that Dr. McReynolds has reported a series of cases in which he has done open reduction of these fractures.

He pointed out two principles. The first is that almost all the comminution of these fractures of the os calcis is on the lateral side, while on the medial side there is usually just one fracture line. This is important. Most surgical procedures for open reduction approach the os calcis from the lateral side and attempt to piece the fragments together and compensate for the compressed cancellous bone by insertion of bone grafts. Dr. McReynolds pointed out that on the medial side there is a practically intact, solid wall of the os calcis with just one fracture line through it.

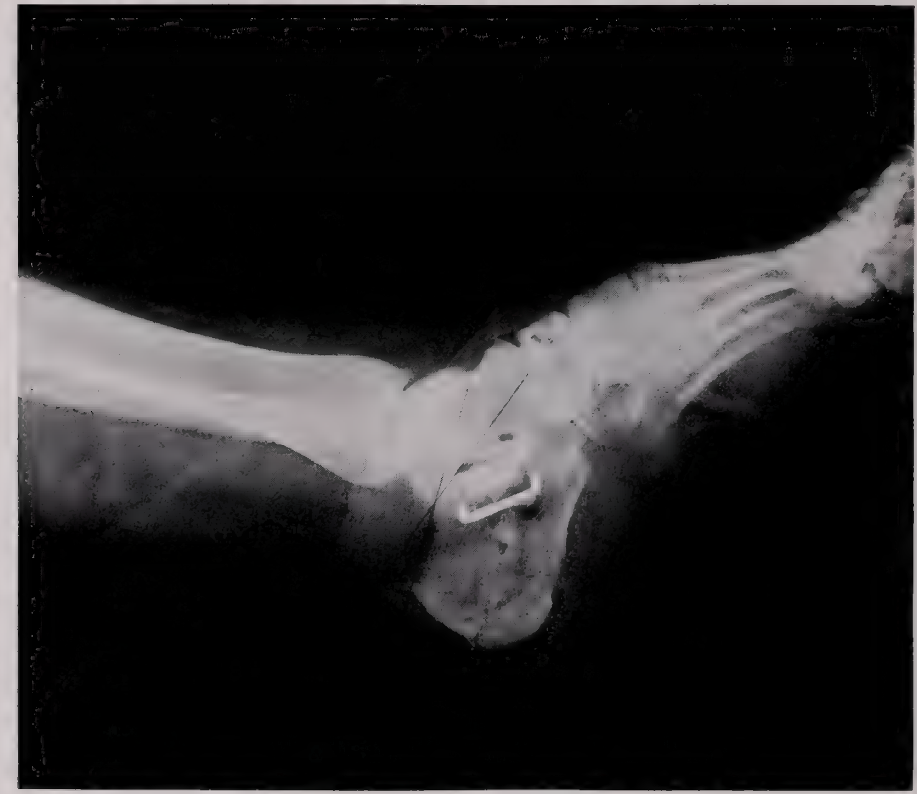

Fig. 2—Lateral view of fractured left os calcis at time of open reduction via medial approach and fixation with one Vitallium staple. Tuber joint angle is now 25 degrees.

His second point is that the os calcis is made wider by the fracturing force. This increased width causes the calcaneus to impinge on the peroneal tendons and on the malleoli and is the cause of some, if not all, of the postfracture symptoms these patients have. You can see on the roentgenograms that the lateral displacement on the anteroposterior view is moderate. You can also see that it is on the lateral side. If you look closely, and are thinking about it, you can see that the medial cortex of the os calcis is relatively intact and not comminuted.

We used Dr. McReynolds' method of open reduction on this fracture (Figure 2). It is absolutely essential that the approach be made from the medial side, so that you can see the medial side of the os calcis and rather easily reduce the fracture and then hold it with one or two staples. In this case it was held with one staple. The tuber angle has been almost completely corrected; then, after the reduction of the fracture, manual compression of the sides of the os calcis reduced the explosion-type enlargement of the lateral side of the calcaneus.

Dr. Chiroff: Thirteen days after the operation described by Dr. Henderson, the extremity was placed in a short-leg cast and the patient was allowed up on crutches without weight bearing.

Dr. William H. Bickel:* How do you hold the fracture while you are doing the internal fixation?

Dr. Henderson: It is fairly easy to do by using some type of a pry.

Dr. Bickel: The Steinmann pin is not used in the os calcis?

---

*Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

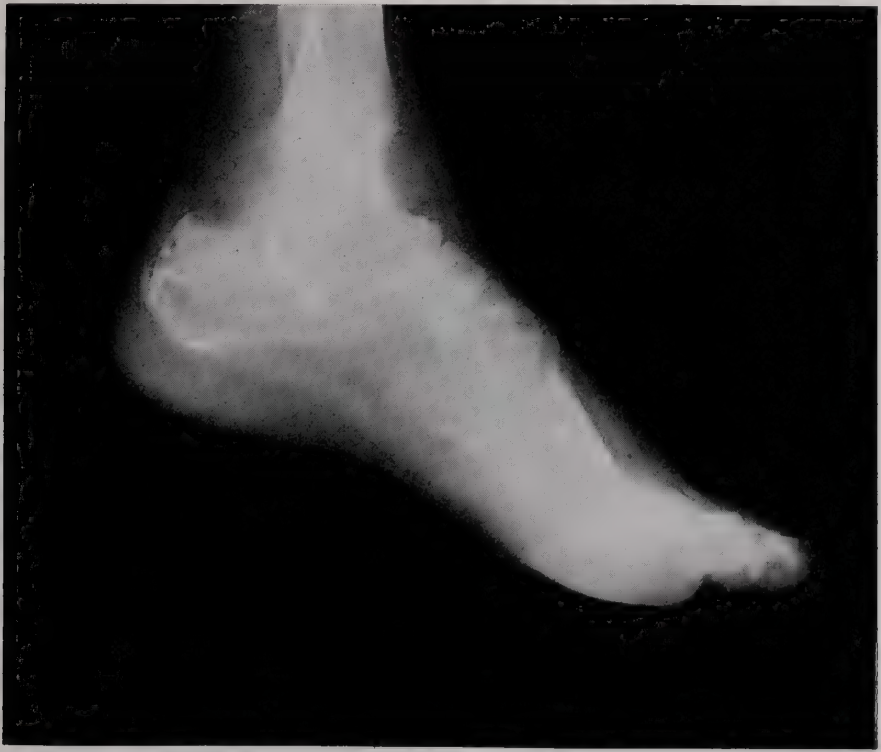

Fig. 3—Lateral view four months postoperatively. Patient was free of pain and had no swelling of foot even after walking all day.

Dr. Henderson: No. The advantage of the medial-side approach is that you have an intact cortex which you can lever into position and which is stable, once reduced and fixed with the staple.

Dr. Chiroff: The patient was allowed to start weight-bearing 13 days postoperatively. Four months after injury, roentgenograms showed good union of the fracture (Figure 3). She was seen here for follow-up examination again at six months after the injury (Figure 4).

Dr. Henderson: At the time I last saw this patient, she was walking without pain. She was still not able to walk on her toes satisfactorily, but she had a full range of motion in her ankle joint. There was about 10 or 15 degrees of motion at the subastragalar joint and this was painless. I anticipate that within the next few weeks or months she will be able to walk on her toes. She has no swelling in her foot.

Dr. McReynolds has now operated on 11 heels in nine patients and has used a bone graft in only one. The only problem in the medial approach is to retract the neurovascular bundle and to avoid the cutaneous nerve that runs down the medial side of the heel. When he approaches the heel on the medial side, he pries the fragment into position and then compresses the heel laterally. He usually uses just one staple but sometimes needs two. He applies a walking, short-leg cast approximately two weeks postoperatively and allows full weight-bearing, with immobilization for about six weeks.

Of these 11 heels, one required a subastragalar arthrodesis. In another there was so much comminution that Dr. McReynolds did a bone graft; but he thinks now that this was not necessary. The average loss of the tuber angle was only 11 degrees, and all nine patients returned to work. The only complication is that the patients do not have normal subastragalar motion (I do not think we could expect this).

I have been doing open reductions on minimal-displacement fractures of the os calcis from the lateral side, but apparently it is a much more extensive

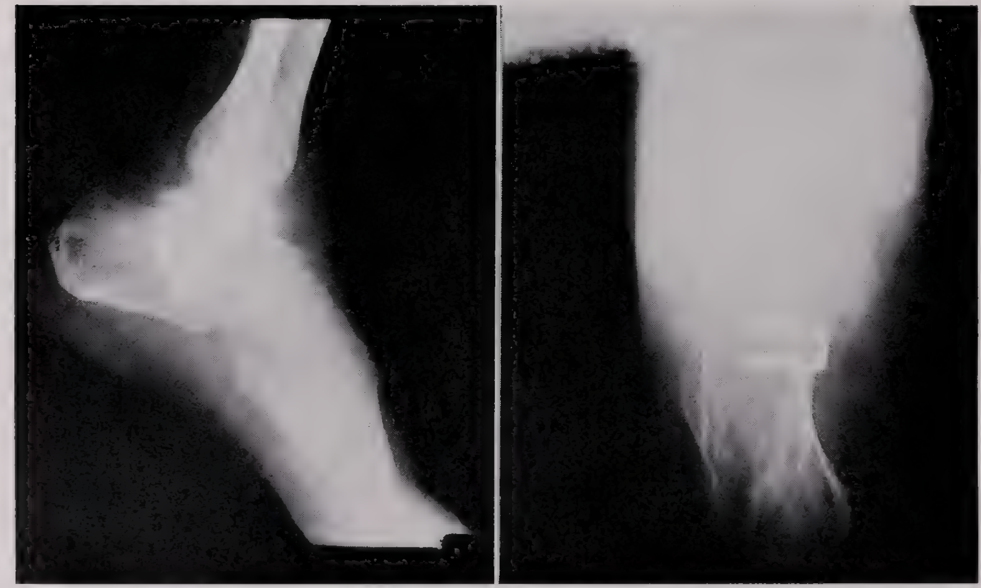

Fig. 4—At six months postoperatively. (Left) Lateral view shows tuber joint angle of 30 degrees. Patient continues to be free of pain. There is approximately 15 degrees of motion in subtalar joint. (Right) Tangential view shows excellent reestablishment of contour of bone.

operative procedure than the one described by Dr. McReynolds. The other advantage to his method is that you get good secure fixation, you can apply a walking cast, and the patients do not get the disuse osteoporosis we see in many patients treated by the other methods.

Dr. Paul R. Lipscomb:* Do you retract the neurovascular bundle superiorly or inferiorly?

Dr. Henderson: Superiorly. Dr. McReynolds makes the incision inferior to the neurovascular bundle.

Dr. Bickel: Did he think there was ever a necessity for opening laterally to put a big fragment back, one that he could not reduce from the medial side?

Dr. Henderson:

In the cases which he reported this was not necessary, but he apparently manipulates or compresses them rather vigorously; waits a few days for the swelling to subside; then casts the foot with the ankle in neutral position, and starts weight-bearing in two to three weeks.

Dr. Mark Coventry:†

I heard and enjoyed Dr. McReynolds' paper and thought his method was surely worth trying. The main point is that he uses the reduced and stable medial cortex of the os calcis as a fulcrum against or around which he molds the rest of the fracture fragments into proper place. Is that the concept you got out of it?

Dr. Henderson:

Yes, that is the understanding I got. The roentgenograms he presented at the meeting in Memphis showed excellent reductions and were quite impressive.

Robert L. Feldmann, M.D.

This cover was reproduced from a painting by Dr. Robert L. Feldmann, which received a Blue Ribbon at the AMA Art Exhibit in San Francisco in June, 1968.

"Eastern Shore" had its genesis during a trip taken by Dr. Feldmann and his youngest daughter. They had traveled from York across the Bay Bridge to Cambridge, Maryland, in search of sea gulls for purposes of painting. On the eastern shore by Hoople's Island, they found a crab factory and a number of desirable scenes. The painting from which the cover picture was taken was inspired here.

Dr. Feldmann's formal training in art was in charcoal during his junior and senior years of college. He belongs to a group of doctors in York who are cultivating their talents in painting. Water color remains his medium of choice.

He is a fellow in the American and Pennsylvania Academies of Ophthalmology and Otolaryngology and practices otolaryngology in York, Pennsylvania.

The Emergency Physician

The increasing patient loads in emergency departments across the country has underscored the need for a new type of physician—a specialist in emergencies: The Emergency Physician.

To assist this new breed of physicians the American College of Emergency Physicians was organized in August, 1968.

A nucleus of physicians—both from full-time and part-time emergency care groups in Michigan—chartered the American College of Emergency Physicians and have organized the College on a nationwide basis.

One of the main purposes of the College is to improve emergency services rendered to the patient. Other aims of the College are: to encourage and implement the training and continuing education of emergency physicians; to promote policy which preserves the integrity of private practice; to promote coordination of community emergency care facilities and personnel; to advance the ethical standards of the private practice of Emergency Medicine and Surgery.

For information write: Executive Secretary, American College of Emergency Physicians, 120 West Saginaw Street, East Lansing, 48823; or the representative in your area—Robert Ersek, M.D., 8806 Minnetonka Blvd., St. Louis Park, Minnesota 55426.

Seminar: Simulation of Biological Systems

A one-week, intensive seminar in the simulation of biological systems will be given July 14-18 (inclusive) 1969 at the EAI Los Angeles Analysis and Computation Center. The seminar will emphasize the development of models suitable for use on modern analog/digital/hybrid computers, without stressing, unduly, the details of programming any given type. Computer demonstration of various models with "hands on" participation will be included.

The seminar will cover the cardiovascular system, artificial kidneys, fluid and electrolyte distribution, hormonal control systems and neuronal and neuromuscular systems. The lecturers will include members of the Faculty, University of Southern California and the RAND Corporation. The fee of $280 will include all required notes and textual material.

For further information contact: Manager of Education and Training, Electronic Associates, Inc., Los Angeles Computation Center, 1500 E. Imperial, El Segundo, California 90245.

Otolaryngology Clinics

STARTING WITH this issue of MINNESOTA MEDICINE the Department of Otolaryngology of the University of Minnesota Medical School and Hospitals will sponsor an on-going series of brief and practical articles designed primarily to be of interest to the family physician. These Otolaryngology Clinics will be written by members of the departmental faculty with an occasional invited contributor.

Judging from two previous surveys conducted in the states of Minnesota and Iowa, the family physician spends an average of twenty per cent of his time dealing with disorders as they affect the ear, nose, throat, maxillofacial area and adjacent regions of the head and neck. This can range anywhere from a red-hot acute otitis media to laryngeal cancer.

An attempt shall be made to keep these articles brief and informal. Suggestions from the Profession for future topics will be greatly appreciated.

The Nature of Otolaryngology

THIRTY YEARS AGO, the training in otolaryngology required for eligibility for Board certification was an 18-month period of residency training in an approved hospital or several years of apprenticeship.

The specialty of otolaryngology deals with the upper respiratory tract and its adnexa. This area includes the nasal spaces and maxillae, the ear connected through the eustachian tube, and the entire throat. The latter includes the structures in the nasopharynx, the oropharynx (which includes the oral cavity, the tonsils, and the soft palate) and the laryngopharynx, of which the larynx and the esophageal introitus are the principal areas.

Even though separate areas are involved which suggest special titles such as otology, rhinology and laryngology, the term otolaryngology is appropriate as a simplified title in that all three areas are connected by the upper respiratory tract and often share in the morbidity associated with infections anywhere in this tract. Some now prefer the term "otorhinolaryngology" to include the field of rhinology.

Broncho-esophagology became part of otolaryngology because of technical difficulties encountered in an adequate visualization of the bronchi and esophagus.

Prior to the advent of the antimicrobials, the major activity of otolaryngologists was concerned with suppuration and its complications in the upper respiratory tract.

Obviously, much less time is needed today to combat infection, and many of the old complications of upper respiratory suppuration are now relative rarities. Research and technical advances by otolaryngologists have been as dramatic as any specialty and have had a strong impact on progress.

In otology the use of the operating microscope has brought new gains in stapes surgery for otosclerosis and in reconstructive middle ear surgery after damage by chronic suppuration. The evaluation of hearing loss and an appreciation of the systemic and neurologic disorders has contributed to the advances in the field of otology.

In the field of rhinology functional disorders and allergic problems are more commonly diagnosed, better understood and managed now than prior to the antimicrobial era.

Reconstructive surgery of the nasal pyramid caused by injury or by improper development is now performed for chronic obstruction as well as for external deformity. It is a natural counterpart of the maxillofacial surgery for oncologic and traumatic disorders that constitutes an important field in otolaryngology.

In laryngology and bronchoesophagology practically the only disorder of the larynx that has decreased in incidence and severity is obstructive laryngitis caused by inflammatory swelling of the glottis. Antimicrobials, steroids and the management of these cases in an atmosphere of high humidity and controlled temperature have lessened the morbidity and the mortality.

The relative frequency of tracheostomy has increased. It is often performed early and electively in the better management of the hypoxic states that result from the accumulation of secretions in the trachea and bronchi.

Today minimum approved residency training in otolaryngology covers a period of four or five years.

There is abundant evidence that otolaryngology is organized to continue the remarkably accelerated progress of the past two decades. Its special societies are dedicated to research and education.*

Progress

Progress: When you're just getting used to something and somebody invents something better that you won't have time to get used to before somebody invents something better.—Howard Blake

Man is born with his hands clenched, but his hands are open in death, because on entering the world he desires to grasp everything, but on leaving, he takes nothing away.—The Talmud

Otalgia

Otalgia can be either primary or secondary. Primary otalgia refers to ear pain resulting from pathological conditions directly affecting the ear; secondary otalgia is that which is referred to the ear. Fifty per cent or more of all pain experienced in the ears of adults originates from another source. It is important to remember that otalgia may not be proportional in seriousness to the disease causing it.

Sensory Innervation of the Ear

Contributions from the Vth, VIIth, IXth and Xth cranial nerves and the cervical plexus provide afferent pathways for transmission of stimuli from the auricle, external auditory canal, middle ear, and immediately adjacent areas.

The auriclotemporal branch of the mandibular division of the Vth nerve supplies the skin of the tragus, the anterior and superior wall of the external auditory canal and sometimes the anterior limb of the helix and a portion of the crus. The auricular branch of the Xth nerve (Arnold's nerve) communicates with a branch of the IXth nerve and the VIIth nerve, and together these supply the concavity of the concha, posterior portion of the external auditory canal and corresponding segment of the external surface of the tympanic membrane, and a small area of skin on the posteromedial aspect of the auricle and adjacent mastoid region. The posterior branch of the great auricular nerve supplies the greater portion of the posterior surface of the auricle and the more posterior part of the lateral surface. There is overlap and communication with the lesser occipital nerve on the mastoid region. The innervation of the external surface of the tympanic membrane corresponds to that of the auditory canal. The tympanic branch of the IXth nerve supplies the inner aspect of the tympanic membrane.

The tympanic plexus constitutes the sensory innervation of the middle ear. The plexus is formed by the tympanic branch of the IXth nerve (Jacobson's nerve) and the superior and inferior cortico-tympanic branches of the sympathetic plexus of the internal carotid artery. One can therefore see, because of the complicated ramifications of the various nerves, that the cause of otalgia is often difficult to locate.

Etiology

Otalgia may have multiple causes (Table), and the diagnosis may be made only if a detailed examination is carried out.

External Ear and Canal

The cause of pain originating from the external ear and canal is easily recognized in most instances. An exception to this may be a very early neoplasm of the external canal. Examination of the external canal may be normal grossly, but if careful palpation of the quadrants of both the bony and the cartilaginous canal is carried out under adequate visualization using a tightly wound cotton-tipped wire applicator, the pain may be elicited.[1] Biopsy of the areas of pain should not be delayed because of the possibility of an early

TABLE

Causes of Ear Pain

Primary (Ear)

A. External Ear
   1. Furunculosis
   2. Foreign body in the external ear canal
   3. External otitis
   4. Abscess of auricle
   5. Perichondritis of auricle
   6. Eczema of the meatus
   7. Impacted cerumen
   8. Frostbite of auricle
   9. Herpes simplex and herpes zoster oticus
   10. Malignant and benign growth of external ear
   11. Fungal infections (otomycosis)
   12. Acute myringitis and myringitis bullosa
   13. Trauma of tympanic membrane and external canal

B. Middle Ear or Mastoid
   1. Acute otitis media
   2. Acute mastoiditis
   3. Acute aero-otitis media (barotrauma)

B. Middle Ear (continued)
   4. Acute eustachian tube obstruction
   5. Complications of otitis media and mastoiditis
      a. petrositis
      b. facial paralysis
      c. labyrinthitis
      d. inner ear deafness
      e. subperiosteal abscess
      f. extradural abscess
      g. subdural abscess
      h. brain abscess
      i. venous sinus thrombophlebitis
      j. meningitis
   6. Malignant and benign growth of middle ear and mastoid process

C. Idiopathic (tic-like pain confined to the ear)
   1. Geniculate complex of the VIIth nerve
   2. Tympanic branch of the IXth nerve

Secondary (Referred)

A. Larynx
   1. Cancer
   2. Ulceration
   3. Perichondritis and chondritis
   4. Arthritis of circoarytenoid joint

B. Pharynx (naso-, oro-, and hypopharynx)
   1. Pharyngitis
   2. Acute tonsillitis (palatine, lingual, pharyngeal)
   3. Peritonsillar abscess
   4. Retropharyngeal abscess
   5. Ulceration
   6. Post adenoidectomy or tonsillectomy
   7. Nasopharyngeal fibroma
   8. Malignant growth

C. Oral Cavity
   1. Dental neuralgias
      a. dentine exposed, pulp inflamed, or nerves dying
      b. unerupted and/or impacted wisdom or molar teeth
      c. traumatic occlusion of teeth, faulty jaw closure and improper denture fit
   2. Acute diffuse glossitis or stomatitis
   3. Carcinoma of tongue

D. Esophagus
   1. Foreign body
   2. Hiatus hernia
   3. Inflammation
   4. Malignant and benign growths

E. Miscellaneous
   1. Mumps
   2. Acute thyroiditis
   3. Trigeminal neuralgia
   4. Sinuses
      a. inflammation
      b. malignant and benign growth
   5. Temporomandibular arthritis
   6. Erysipelas

E. Miscellaneous (continued)
   7. Raynaud's disease
   8. Chilblains
   9. Postauricular lymphodenitis
   10. Glossopharyngeal neuralgia
   11. Sphenopalatine ganglion cephalgia
   12. Elongation of the styloid process
   13. Involvement of upper three cervical nerves
      a. whiplash injury and other cervical spine lesions
      b. inflammation such as tabes dorsalis or herpes
   14. Angina pectoris
   15. Thoracic aneurysm
   16. Innominate artery aneurysm
   17. Affections of nasal passageway
   18. Affections of lung and bronchus

malignancy. Middle ear affections should be recognized in most instances. Chronic infection of the middle ear does not usually cause ear pain. If pain occurs with chronic otitis media or chronic mastoiditis, an impending or existing complication is present.

Seventh and Ninth Nerve

Tic-like pain confined to the ear is a rare condition which may originate in either the geniculate complex of the VIIth nerve or the tympanic branch of the IXth nerve.[2] Definite diagnosis rests basically on the results of stimulation and section of the nervus intermedius and glossopharyngeal nerves within the cranial cavity, or similar maneuvers applied peripherally to the chorda tympani and Jacobson's nerve in the middle ear.

Tenth Nerve

Referred otalgia, through the superior laryngeal nerve of the vagus, may originate from lesions in the larynx and hypopharynx. Lesions in the area of the palatine, pharyngeal, and lingual tonsils and adjacent tongue may cause ear pain via the glossopharyngeal nerve. A branch of the trigeminal nerve will cause referred ear pain from dental and oral disease.

The manner in which the mandible is attached to the skull provides obvious chances for the condyle to impinge on sensory nerve branches (chorda tympani, auricular branches of the auriculotemporal nerve). Joint destruction does not have to be present to produce reflex pain. In the majority of cases, roentgenograms are normal.

Visceral Organs

Otalgia may be referred from visceral organs to the ear,[3] including the lung and bronchus by way of the bronchial branch of the vagus, esophogeal hiatus hernia, angina pectoris, and aneurysms of the innominate artery or thoracic aorta. Cervical spine lesions may cause referred otalgia from branches of the cervical plexus, principally the second and third cranial nerves.

Summary

1. Pain that is felt in the ear may not originate from the ear.
2. Ear pain of a referred nature requires intensive investigation of the larynx, pharynx, oral cavity, temporomandibular joint, sinuses, esophagus, lung cervical plexus and thoracic vasculature. In other words, any structure in the proximity of the nerves supplying the ear (cranial nerves V, IX, X, Cl-3, and sympathetics and parasympathetics) can refer pain to the ear.
3. Otalgia may not be proportional in seriousness to the disease causing it. A laryngeal carcinoma may cause only vague pain; whereas dental caries may cause severe pain.

Case Reports

The following four patients presented initially to the physician's office with a chief complaint of pain in the ear (otalgia). Two patients proved to have otalgia due to primary disease in the ear, while the other two demonstrated secondary or referred pain to the ear. Another common example of secondary or referred otalgia would be temporomandibular joint dysfunction.

Primary Ear Pain

Case 1

A female patient in her early 50's presented with excruciating right ear pain as her primary symptom. In the past she had received treatment for external otitis from other physicians. Routine otoscopy did not reveal a lesion but, with magnification, a small (3-4mm) irregular growth was noted on the lateral portion of the anterior bony canal wall. The trigeminal neuralgia-like pain was elicited by pinpoint palpation with a cotton-tipped wire applicator. An excision biopsy was performed and a diagnosis of squamous-cell carcinoma made.

Surgical treatment was instituted in July, 1963. This included block excision of the anterior half of the tympanic membrane, the entire anterior canal wall up to the tragus, the superficial lobe of the parotid gland, and the condyle of the mandible. The posterior bony wall was widened maximally with a drill, but a mastoidectomy was not performed. To date, there has been no recurrence of the growth and no further pain.

Case 2

This 37-year-old white female had experienced severe pain in her left ear for the preceding two and one-half years which was refractory to medical treatment. Approximately one year before this admission she had an excision of a small lesion from the left external canal by another physician. This was reported to be a cylindroma. However, postoperatively the pain persisted.

Examination of the left external canal showed it to be clear. The tympanic membrane was intact with normal landmarks. By careful otoscopy, a reddened elevated area in the posterior superior portion of the canal could be seen but no lesion could be identified. The area was very tender to touch as opposed to other parts of the canal. This was thought to be the area from which the previous tumor had been excised.

It was felt that it would be justified to consider a wide excision of this area with perhaps removal of cartilage and bone for exploratory purposes. In September, 1965, by means of a postauricular incision, the entire posterior and superior canal skin was extirpated and the bony canal was drilled down to achieve maximum exposure. A wide margin was excised around the lesion in piecemeal fashion. The pathology report indicated a ceruminoma. The patient has been doing well with no recurrence.

Secondary Ear Pain

Case 3

A male patient in his 50's was found to have squamous-cell carcinoma of the cervical esophagus in December, 1967. The lesion was treated with cobalt^{60}. He did well until January, 1969, at which time he started having dysphagia. Esophogram and esophogoscopy revealed a recurrence of his tumor. A second course of cobalt^{60} was started. After two weeks of therapy, the patient experienced severe left ear pain which awakened him at night and required analgesics for relief.

Examination of the left ear canal and tympanic membrane was normal. The left posterior external ear canal was very tender to palpation with a cotton-tip applicator. The rest of the canal, as well as the right external canal, was non-tender to palpation. Injection of the left external canal with 1% xylocaine with epinephrine, 1:1000, completely relieved the pain. Referred pain along the Xth cranial nerve took place here.

Case 4

A fifteen-year-old girl had a left upper molar extracted two days prior to being seen. She also had an impacted and infected lower molar on the left which was being treated with antibiotics before extraction. The main complaint of the patient was left ear pain. Examination of the external canal and tympanic membrane revealed no pathology. The posterior canal wall was tender to palpation. Injection of the external canal with 1% xylocaine and epinephrine, 1:1000, relieved the pain. Here referred or secondary ear pain occurred along the Vth cranial nerve.

JUDGE ANTIBIOTIC OINTMENTS HERE

Results on skin are final proof of any topical antibiotic's effectiveness

No in vitro test can duplicate a clinical situation on living skin. 'Neosporin' (polymyxin B—bacitracin—neomycin) Ointment has consistently proven its effectiveness in thousands of cases of bacterial skin infection. The spectra of the three antibiotics overlap in such a way as to provide bactericidal action against most pathogenic bacteria likely to be found topically. Diffusion of the antibiotics from the special petrolatum base is rapid since they are insoluble in the petrolatum, but readily soluble in tissue fluids. The Ointment is bland and nonirritating.

Caution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: This product is contraindicated in those individuals who have shown hypersensitivity to any of its components.

Supplied: Tubes of 1 oz., ½ oz. with applicator tip, and ⅛ oz. with ophthalmic tip.

Complete literature available on request from Professional Services Dept. PML.

'NEOSPORIN'®
brand

POLYMYXIN B-BACITRACIN-NEOMYCIN OINTMENT

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, N.Y.

Mild ulcerative colitis may be triggered here...

In mild ulcerative colitis, a number of factors can precipitate an attack: for instance, dietary indiscretion, such as eating raw foods, or emotional overreaction, such as that aroused by financial difficulties. No matter what causes the patient's sensitive colon to "act up," he soon suffers from acute discomfort...and often, from anxiety and apprehension as well. Such patients frequently respond well to adjunctive dual-action Librax® therapy.

Librax combines, in a single convenient capsule, the well-known antianxiety effect of Librium® (chlordiazepoxide HCl) and the dependable anticholinergic/antispasmodic effect of Quarzan® (clidinium Br). Therefore, as Librax helps to relieve the patient's excessive anxiety and reduce his overreaction to stress, it also, at the same time, helps to control hypersecretion and hypermotility, thus relieving spasm and abdominal discomfort.

With Librax, the dosage schedule is simple: 1 or 2 capsules, t.i.d. or q.i.d., will in most cases bring the patient significant relief of both the emotional and physical elements that contribute to his psychovisceral disorder.

Before prescribing, please consult complete product information, a summary of which follows.

INDICATIONS: Indicated as adjunctive therapy to control emotional and somatic factors in gastrointestinal disorders.

CONTRAINDICATIONS: Patients with glaucoma; prostatic hypertrophy and benign bladder neck obstruction; known hypersensitivity to chlordiazepoxide HCl and/or clidinium bromide.

WARNINGS: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering Librium (chlordiazepoxide hydrochloride) to known addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards. As with all anticholinergic drugs, an inhibiting effect on lactation may occur.

PRECAUTIONS: In elderly and debilitated, limit dosage to smallest effective amount to preclude development of ataxia, oversedation or confusion (not more than two capsules per day initially; increase gradually as needed and toler-

or here.

ted). Though generally not recommended, if ombination therapy with other psychotropics eems indicated, carefully consider individual harmacologic effects, particularly in use of po-entiating drugs such as MAO inhibitors and henothiazines. Observe usual precautions in resence of impaired renal or hepatic function. aradoxical reactions (*e.g.*, excitement, stimula-ion and acute rage) have been reported in psy-hiatric patients. Employ usual precautions in reatment of anxiety states with evidence of im-ending depression; suicidal tendencies may be resent and protective measures necessary. Vari-ble effects on blood coagulation have been eported very rarely in patients receiving the rug and oral anticoagulants; causal relation-hip has not been established clinically.

ADVERSE REACTIONS: No side effects or nanifestations not seen with either compound lone have been reported with Librax. When hlordiazepoxide hydrochloride is used alone, rowsiness, ataxia and confusion may occur, specially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally with chlordiazepoxide hydrochloride, making periodic blood counts and liver-function tests advisable during protracted therapy. Adverse effects reported with Librax are typical of anticholinergic agents, *i.e.*, dryness of mouth, blurring of vision, urinary hesitancy and constipation. Constipation has occurred most often when Librax therapy is combined with other spasmolytics, and/or low residue diet.

two good reasons for prescribing LIBRAX®

Each capsule contains 5 mg chlordiazepoxide HCl and 2.5 mg clidinium Br.

Nose clear as a whistle

(THANKS TO DIMETAPP®)

Dimetapp Extentabs® does an outstanding job of helping to clear up the stuffiness, drip and congestion of colds and upper respiratory allergies and infections. Each Extentab keeps working up to 12 hours. And for most patients drowsiness or overstimulation is unlikely. Try Dimetapp. It clearly works.

FOR UPPER RESPIRATORY ALLERGIES AND INFECTIONS

Dimetapp Extentabs®

Dimetane® (brompheniramine maleate), 12 mg.; phenylephrine HCl, 15 mg.; phenylpropanolamine HCl, 15 mg.

UP TO 12 HOURS CLEAR BREATHING ON ONE TABLET

Indications: Dimetapp is indicated for symptomatic relief of the allergic manifestations of respiratory illnesses, such as the common cold and bronchial asthma, seasonal allergies, sinusitis, rhinitis, conjunctivitis, and otitis.
Contraindications: Hypersensitivity to antihistamines. Not recommended for use during pregnancy.
Precautions: Until patient's response has been determined, he should be cautioned against engaging in operations requiring alertness. Administer with care to patients with cardiac or peripheral vascular diseases or hypertension.
Side Effects: Hypersensitivity reactions including skin rashes, urticaria, hypotension and thrombocytopenia, have been reported on rare occasions. Drowsiness, lassitude, nausea, giddiness, dryness of the mouth, mydriasis, increased irritability or excitement may be encountered.
Dosage: 1 Extentab morning and evening.
Supplied: Bottles of 100 and 500.

Clinical Path Conference

Pulmonary Opportunistic Infections after Renal Transplantation

Dr. Thomas Mulrooney:*

A 48-year-old white female was admitted to Hennepin County General Hospital to receive a renal transplant. Chronic renal failure had been present for two years following chronic pyelonephritis. During that two-year period, the patient had been supported by chronic hemodialysis. Two months earlier she had undergone bilateral nephrectomy to assist in the control of hypertension and to prepare her for the transplantation.

The patient was a thin, alert, chronically ill-appearing woman in no acute distress. Her blood pressure was 150/100, her pulse 80 per minute, and her temperature 98°. Mild arteriosclerosis was observed in the optic fundi. The heart was not enlarged, but a loud, harsh, systolic murmur was audible over most of the precordium and was transmitted into the neck. The lungs were clear. Apart from old surgical scars of the abdomen, the remainder of the physical examination was normal.

Laboratory Studies

Laboratory studies included hemoglobin 9.8 grams %; white blood cell count 7800 per cu. mm. with 79% neutrophils, 19% lymphocytes and 2% eosinophils. Serum electrolytes revealed serum sodium 134 mEq/L; potassium 4.8 mEq/L; chloride 94 mEq/L and CO_2 21 mEq/L. Serum proteins, calcium, alkaline phosphatase, bilirubin and fasting blood glucose were all normal. The blood urea nitrogen was 70 mg. %. An EKG showed a first degree A-V block and increased voltage in the left precordial leads thought compatible with left ventricular hypertrophy. A chest roentgenogram was normal.

Hospital Course

On the third hospital day, the patient received the left kidney of a cadaver donor which was ingrafted into the patient's right flank. The surgical procedure was well tolerated and Azathioprine and prednisone were given to prevent rejection.

On the tenth day following surgery the patient experienced a rise in temperature to 103° and developed a non-productive cough. Scattered wheezes and rhonchi were audible in both lung fields. The white blood cell count was 8400 per cu. mm. with 90% neutrophils, 7% lymphocytes and 3% monocytes. The BUN was 132 mg. % and the serum creatinine 2.1 mg. %. Serum electrolyte determinations were again normal. A chest roentgenogram showed bilateral pulmonary infiltrations, particularly involving the hilar areas of the lung. The venous pressure was 15 cm. of water and a circulation time with decholin was 15 seconds. Her intake of sodium in water was restricted and she was treated with furosemide and cephaloridine. Sputum smears revealed a mixture of Klebsiella species and Candida albicans. She continued to receive prednisone 40 mg. daily and Azathioprine 50 to 100 mg. daily.

Over the next several days her condition deteriorated and roentgenograms demonstrated progression of the pulmonary infiltrations. On the 16th day after transplantation an open lung biopsy was performed and Azathioprine was discontinued. Touch imprints of the lung biopsy specimen were stained with Geimsa stain, and organisms suggestive of pneumocystis carnii were felt to be present. The pathologic diagnosis for the lung biopsy was interstitial pneumonitis, and special stains for bacteria, fungi, acid-fast bacilli and pneumocystis carnii were negative. Repeated examinations of sputum for these organisms were also negative and cultures grew Klebsiella and occasional colonies of Candida albicans.

---

*Staff, Department of Internal Medicine, Hennepin County General Hospital.

Following the lung biopsy, the patient was given pentamadine isethionate 225 mg. daily as well as cephalothin and methyl prednisolone. Because of deterioration of renal function and suspected rejection, she received a course of radiotherapy to the transplant site and her corticosteroid dose was increased to 100 mg. of methylprednisolone daily. With this treatment program she became afebrile although her white blood cell count remained near 15,000 per cu. mm. with about 99% neutrophils. She became less dyspneic, and gradual clearing of the pulmonary infiltrates was observed on chest roentgenograms. However, her renal function became progressively impaired and hemodialysis was necessary. It was decided that her transplanted kidney had been conclusively rejected, and 12 days after her lung biopsy the renal transplant was removed.

The patient did well for three days and then abruptly developed increasing dyspnea. Rales were audible over both lung fields. Her chest films showed progression of the diffuse pulmonary infiltrations. During the next several days her air hunger became steadily worse and no improvement was observed despite increases of corticosteroids and administration of chloramphenicol, colistin, and gamma globulin. She became severely hypoxic, requiring tracheostomy and assisted ventilation with a mechanical respirator. Despite the administration of 100% oxygen, her arterial tensions were never in excess of 50 mm. of mercury. On the ninth day following removal of the transplanted kidney, the arterial oxygen tension was 48 mm. of mercury, CO_2 tension 32 mm. of mercury, and pH 7.53. At this time, the hemoglobin was 11.9 grams % and the white blood cell count 5600 per cu. mm. with 96% neutrophils and 4% lymphocytes. Serum electrolytes were normal except for a CO_2 of 32 mEq/L. The BUN was 69 mg.% and the creatinine 3.9 mg. %. Thereafter, the patient became increasingly unresponsive and two days later she expired. Death occurred 37 days after the renal transplantation and 11 days after removal of the rejected kidney.

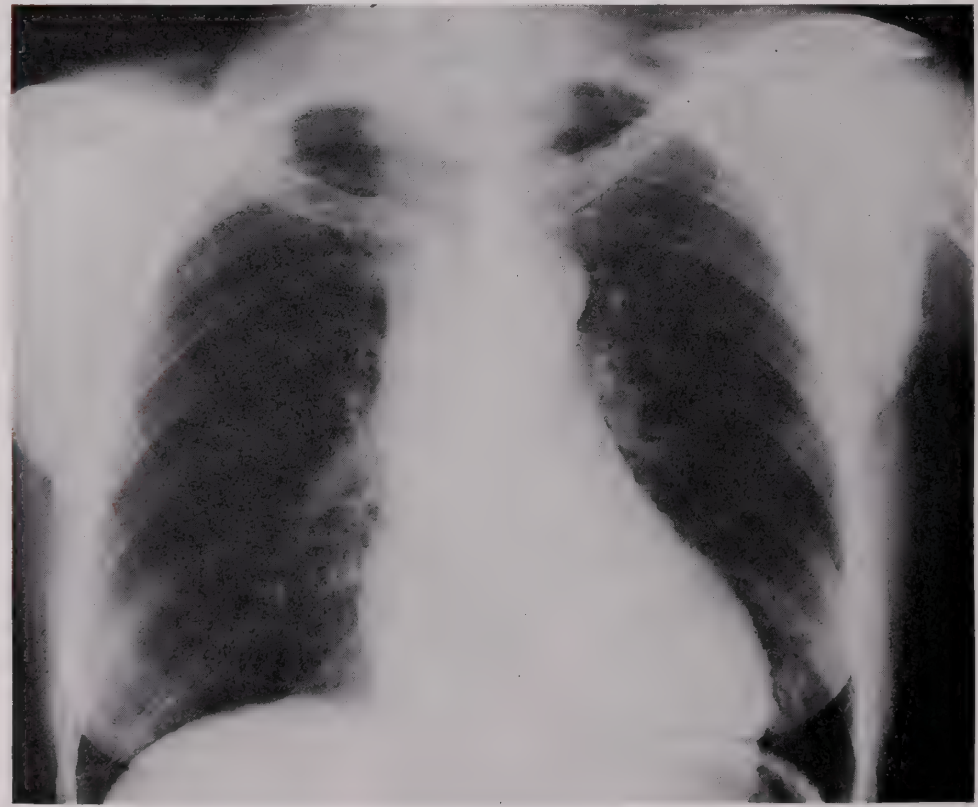

Fig. 1—Chest roentgenogram showing slight pleural effusions without pulmonary infiltration.

Clinical Discussion

Dr. James Lillehei:*

The problem presented by this case is essentially that of a 48-year-old white female who was admitted to the hospital to receive a renal transplant after two years of chronic hemodialysis. Two months before this hospitalization she had had a bilateral nephrectomy to assist in the control of hypertension. Significant physical findings included a slight elevation of blood pressure and a systolic heart murmur. The lungs were clear at that time.

The laboratory studies revealed an anemia with a normal differential count. Blood chemistries were normal with the exception of a BUN of 70 mg.%. She had an electrocardiogram abnormality, namely a first degree A-V block and findings that were suggestive of left ventricular hypertrophy. Her chest roentgenogram was normal.

On the third hospital day she underwent renal transplantation with a cadaver kidney and the surgical procedure was well tolerated. On the tenth day following surgery her course became complicated by fever and a non-productive cough. The white blood cell count remained essentially normal except for a more prominent shift to the left. Her BUN was markedly elevated to 132 mg.%. Then for the first time, about 10 days after the procedure, the chest roentgenogram showed bilateral pulmonary infiltrations. I assume that congestive heart failure was considered at that time since a venous pressure and circulation time were found to be normal. I wonder if this might not be an appropriate time to have the x-ray studies?

Radiological Findings

Dr. Mario Pleigo:†

A large number of x-ray studies were done on this patient. All chest

†Associate Radiologist, Hennepin County General Hospital.

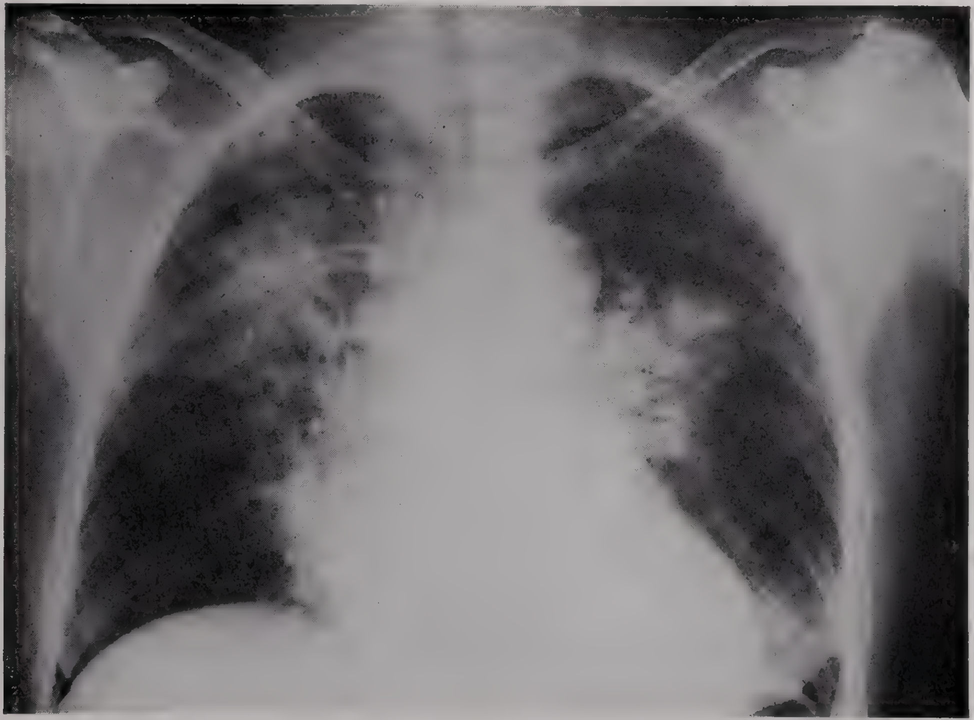

Fig. 2—Chest roentgenogram with bilateral alveolar infiltrations fanning out from the hilar areas to the upper lobes.

roentgenograms show cardiac enlargement with left ventricular predominance and what was interpreted as central pulmonary congestion. On a film in early December (Figure 1) bilateral slight pleural effusions were noted, and then on the film dated December 15 (Figure 2) we began seeing nodular mottled densities in both hilar areas. It is difficult to differentiate these findings from pulmonary edema or uremic pneumonitis, and I am sure those diagnoses were considered. We could not give a definite suggestion of an etiologic agent for the bronchopneumonia from the appearance of the chest x-ray, although lung transplant syndrome was considered.

Hereafter, the radiologist must evaluate the changes on serial roentgenograms and the process appears to evolve into an infiltrative pneumonia with upper lobe involvement that we could not distinguish from acute pulmonary tuberculosis. As the x-ray findings evolve they appear to show a perivascular pattern with an alveolar infiltration, particularly in the upper lobes. Some component of uremic pneumonitis could be present as well.

Dr. Lillehei:

The x-ray findings appear non-specific; however, sputum cultures revealed Klebsiella Enterobacter species sensitive to an antibiotic being used. She continued to receive prednisone in moderate dosage and Azathioprine in 50-100 mg. daily dosage. Over the next several days a progression of the pulmonary infiltrations occurred, and on the 16th day after transplantation, the patient had an open lung biopsy and treatment with Azathioprine was discontinued. The biopsy specimen revealed an organizing interstitial pneumonitis, thickening and fibrosis of the interalveolar septa, and a predominantly mononuclear cell infiltrate. Cultures of the biopsy specimen showed only Candida albicans. Special histochemical techniques failed to reveal an infecting organism. However, following the biopsy the patient was treated with pentamadine isethionate since pneumocystis carnii cysts were suspected on a Geimsa stain. It is very important in this setting to have imprint touch preparations from the surface of the lung biopsy specimen, since this diagnosis can sometimes be made. The main advantage of this technique is that the specimen can be stained and examined immediately and assist the physician with therapeutic efforts. With some opportunistic pathogens, particularly pneumocystis carnii, one or two days could make a difference between the patient living or dying. There is good reason to emphasize doing lung imprints as was done here.

In the meantime, the patient was felt to be rejecting her cadaver transplant kidney. A course of radiotherapy was given to the transplant site and the steroid dosage was increased. With this treatment program she became afebrile and less dyspneic, with some improvement in the pulmonary infiltrations. Of course it was not clear which of the medications she was being given was accounting for the improvement of the x-ray picture. By 12 days after lung biopsy, renal rejection was felt to be definitely established and the cadaver transplant was removed. She did well for a few days and then became increasingly dyspneic. Pulmonary findings increased and the infiltrative process in the lung became more generalized. Thereafter, her course was relentlessly downhill in spite of drugs and mechanical ventilation.

Uremic Pneumonitis

Uremic pneumonitis has been mentioned for several years as producing this type of picture. However, we have great difficulty in separating uremic pneumonitis from pulmonary edema, and now it is becoming increasingly difficult to distinguish this form of pneumonitis from the opportunistic pneumonias. Notice that the patient's BUN was modestly elevated at 69 mg.%; so it is difficult to attribute the progression of the pulmonary infiltration to uremic pneumonitis.

Lung Transplant Syndrome

Lung transplant syndrome is a term which has been applied to this type of clinical situation, and the criteria for the diagnosis include an x-ray picture of lung infiltration associated with renal rejection and pathology which is immunologically non-specific. This syndrome frequently responds to steroid therapy. It is felt that transplantation lung is some sort of immunologic phenomenon based on the similarity of antigens from the lung basement membrane and renal tissue. Therefore, when the kidney is being rejected, the lung takes part in the immunologic insult. The non-specific findings on lung biopsy would be compatible with the diagnosis of transplantation lung. The argument that this is an immunologic phenomenon rather than an opportunistic infection is based on the response to high dose steroids. In this case, I would discard this diagnosis because a response to steroids does not necessarily mean that an immunologic phenomenon is occurring.

We now know from our early experience with opportunistic infections that the use of steroids may make the infiltration disappear and the patient may be made afebrile and gain a sense of well-being. We have had one patient with pneumocystis carnii pneumonia who had a very dense pulmonary infiltrate that responded to increased steroid dosage by completely disappearing within one month. Therefore, the disappearance of the infiltration with steroids should not be used to indicate that the disease process was an immunologic phenomenon. I do not know whether there is such a thing as transplantation lung; I would keep my mind open at this point. At the present time, I think that most of these pulmonary infiltrations are related to infections with specific organisms rather than an immunologic phenomenon.

Opportunistic Infections

The pattern in this patient is becoming increasingly familiar in certain hospitals in which transplantation programs are in progress. In these centers. immunosuppressive drugs are being given for treatment of a variety of conditions, including leukemias, lymphomas, and occasionally carcinomas.

At this point, I would like to put in a plea for the use of needle biopsy of the lung in this type of patient with a progressive lung problem. In the presence of these overwhelming opportunistic infections, a definite diagnosis must be made since the treatment for each condition is significantly different. The treatments for these opportunistic organisms are frequently quite toxic, and it is not going to be possible to put patients on a number of these toxic agents at any one time. I think we are going to have to make specific diagnoses and individualize therapy in each case.

In the Table, you will notice the autopsy findings in a series of 60 patients who died after renal transplantation at the University of Colorado Hospitals.[1] The authors thought that the organism listed at the left hand margin was the cause of death; the organism in the second column was found in association but felt to be incidental. In 15 of these patients, the infecting organism causing death was pseudomonas species. This bacterial infection caused death in a quarter of the patients since no adequate antibiotic agents to treat pseudomonas infections were available. The remainder of the pulmonary opportunists listed in the table can cause pulmonary infiltrations similar to those seen in our case. A number of pathogenic fungi, pneumocystis carinii, cytomegalic inclusion virus, and other bacterial organisms were frequently noted.

TABLE
Organisms Recovered at Autopsy (Sixty Patients)

	Cause of Death (no.)	Ancillary Infection (no.)
Pseudomonas	15	1
Paracolon, Klebsiella, Esch. coli	7	2
Staphylococcus, Pneumococcus	3	
Nocardia	3	
Aspergillus	7	
Candida	9	6
Histoplasma	1	1

Cytomegalovirus		30
Herpes zoster		1
Herrellea		1
Serratia		1
M. tuberculosis		2
Sporozoon, unidentified		1
Totals	48	53

Pneumocystis Carinii

We have now had six patients with immunosuppressive drug therapy who were found to have pneumocystis carinii infection. The diagnosis was made on two occasions by finding the organism in the sputum after staining with methenamine silver technique. When we cannot make a diagnosis by examination of the sputum, and the patient is extremely ill, we do a needle biopsy; and we have obtained a positive diagnosis in four instances. One of our patients had an open biopsy and the other three a needle biopsy. We have not missed a case of pneumocystis carinii pneumonia with a needle biopsy as yet. Aspiration of the pulmonary infiltrate transthoracically with a #18 needle has been unsuccessful in demonstrating pneumocystis in our hands.

Cytomegalic Inclusion Disease

Cytomegalic inclusion virus and pneumocystosis probably occur in many normal individuals as a latent infection. Autopsy studies on patients dying of a variety of diseases reveal a frequent association of viral inclusion bodies and pneumocystis. Notice that 57% of the autopsy series from the University of Colorado had associated cytomegalic inclusion virus with or without other pathogenic agents.

I might also mention that serologic testing for cytomegalovirus is worthwhile in young individuals because their incidence of titres to cytomegalovirus is low. In adults, this is not of much help since it has been reported that up to 80% of the patients over 35 have positive titres to cytomegalic inclusion virus. Apparently most of us come in contact with cytomegalovirus during our early life and a positive serologic test is not diagnostic.

Although cytomegalic inclusion virus was not considered a cause of death in the patients in the University of Colorado series, I would consider this agent as possibly being lethal in this case. I would like to remind you that it is very difficult to decide exactly what infectious agent causes death. The reason for this is that almost all of the organisms which can act as pulmonary opportunists can be found in various clinical situations or in normal persons. The reason I feel that cytomegalovirus can cause pneumonia and death relates to some case reports in the literature plus at least one of our cases of proven pneumocystis carinii infection in a patient with leukemia. We found the pneumocystis and treated the patient for pneumocystosis; he did not respond and died. This represented our first failure treating pneumocystis after two good responses, and at autopsy cytomegalic inclusion virus was found in large numbers in the lungs in addition to some persisting pneumocystis. I am beginning to think that cytomegalovirus kills patients under these circumstances.

Dr. Robert L. Strom:*

Dr. Lillehei, although it is not mentioned in the protocol, it is notable that this patient developed a vesicular eruption on the right flank and also on the mucous membrane of the vulva which was felt to be consistent with varicella-zoster virus infection.

Dr. Lillehei:

That is a good point because this kind of patient again is very susceptible to herpes virus and varicella-zoster virus as the result of altered immunity. Other viral agents and pathogens may also be found. Mycoplasma pneumonii infections have been suspected but not verified in a small study in this patient population. Nevertheless, patients with mycoplasma pneumonii infection often have cold agglutinins demonstrable in their serum. It is of interest that nearly one third of the patients who died after transplantation at the University of Colorado showed the presence of cold agglutinins in their serum and yet mycoplasma pneumonii were not found.

In conclusion, I believe that the patient developed an opportunistic infection perhaps due to multiple organisms in association with immunosuppression. The x-ray picture and laboratory findings, although helpful, do not allow me to isolate a specific bacterial or fungal agent which might have caused death. I feel that it is highly likely that cytomegalic inclusion disease will be found in the autopsy.

Clinical Diagnosis: Status post rejection of cadaver homotransplant.
Fungal and bacterial infection of the lung after immunosuppression.
Cytomegalic inclusion disease of the lung.

Pathology

Dr. Strom:

The deliberate suppression of immunity in order to favor transplanted organ survival has now introduced a wide variety of remarkable infections, particularly pulmonary opportunistic infections. It is possible that these infections will become the limiting factors to the success of transplant procedures. An increase in prevalence of overwhelming pulmonary mycotic infection lays a burden on both the clinician and the diagnostic laboratory. Without discerning clinical judgment and awareness, the diagnosis of these infections may be made only by the pathologist at post-mortem examination.

---

*Associate Pathologist, Hennepin County General Hospital.

On post-mortem examination, ruptured vesicles were noted over the right flank and vulva and these were found to be subepidermal vesicles characteristic of those caused by varicella-zoster virus. Some of the bullous lesions on the right flank were secondarily infected with the pseudomycelia of Candida species. The association of varicella-zoster virus skin vesicles localized to a skin dermatome which has been given therapeutic radiation in a patient undergoing immunosuppression has been well described.[2] Presumably this is due to activation of a latent virus infection in the dorsal root of the affected dermatome. Additional studies need to be done before the true nature of the pathologic process, which allows expression of latent virus infections, can be illucidated.

Each chest cavity contained approximately 500 cc. of serosanguineous fluid. The lungs were extremely heavy, with a combined weight of 2300 grams.

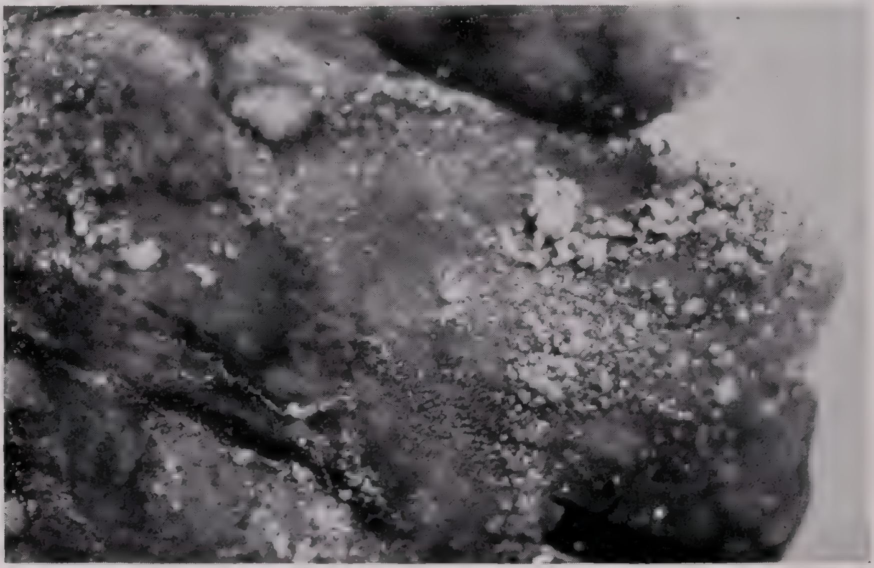

Fig. 3—Discrete granulations and encrustation of pleural surfaces due to Candida albicans.

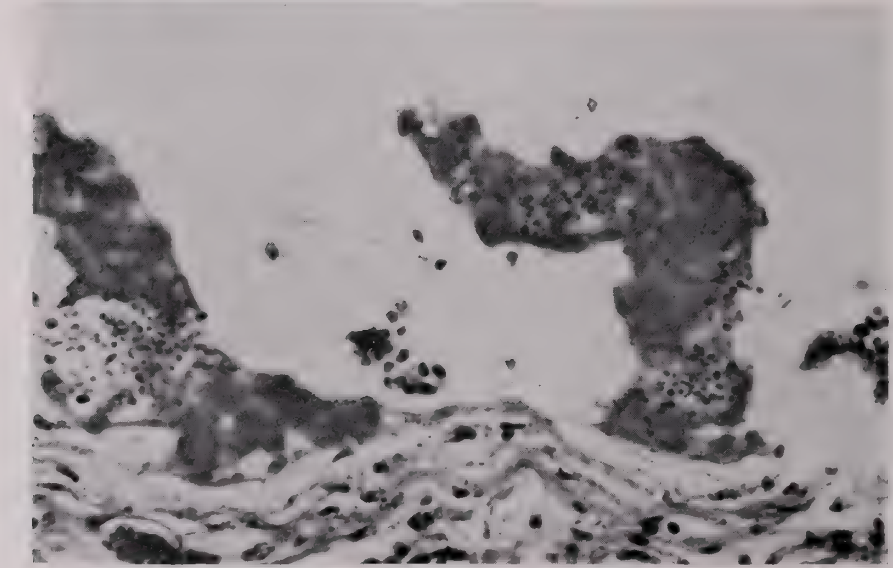

Rig. 4—400X Gram-positive blastospores and pseudohyphae due to Candida albicans infections of the pleural surface.

The lung surfaces were indurated to palpation and many discrete rounded granulations were noted on the pleural surfaces (Figure 3). These unusual small, round granulations were unfamiliar to us and we did not appreciate their etiology until after microscopic examination of the tissue. In some areas, the pleural surfaces showed a light yellow encrustation, and we now know that this represents candidiasis of the pleural surface. Budding pseudohyphae and blastospores, which were gram-positive and compatible with Candida albicans infection, were present on the pleural surface (Figure 4).

I think one of the problems with needle biopsy is that we are biopsying at the periphery of the lung, while many of the opportunistic infections occur as central infarctions in the deep lung tissue. As seen on x-ray and in this cut surface of the lung at autopsy, much of the lesion is centrally placed (Figure 5). The zone of infarcted pulmonary tissue is seen centrally, and proliferating fungus with invasion of pulmonary veins and associated focal arterial thrombi are seen on histologic examination. On microscopic examination of the lung tissue, we see proliferating fungal hyphae standing out against a background of lung alveoli and the hyphae appear gram-negative. The angle of the branching of these septate mycelia is approximately 45°, and they are highly suggestive of mycelia of Aspergillus species (Figure 6). Budding pseudohyphae of Candida species are similarly occasionally observed in the lungs. In addition, cytomegalic inclusion virus was present in the lung sections with hemorrhage into the adjacent alveoli (Figure 7). Here we see ballooned-up alveolar lining cells with eosinophilic cytoplasm and a large red intranuclear inclusion surrounded by a halo with margination of the chromatin around the periphery of the nucleus. The red cytomegalic inclusion bodies in the nucleus are made up of DNA and virus material. Some of the cytomegalic inclusion cells we observe also contain basophilic inclusions in the cytoplasm. These are felt to be a combination of DNA and RNA.

The heart weighed 450 grams and a small mural thrombus was present at the apex of the left ventricle. Within the septum and in the left ventricular wall, we observed multiple small round areas of hemorrhagic necrosis with yellow centers and hemorrhagic margins. Microscopic sections taken through

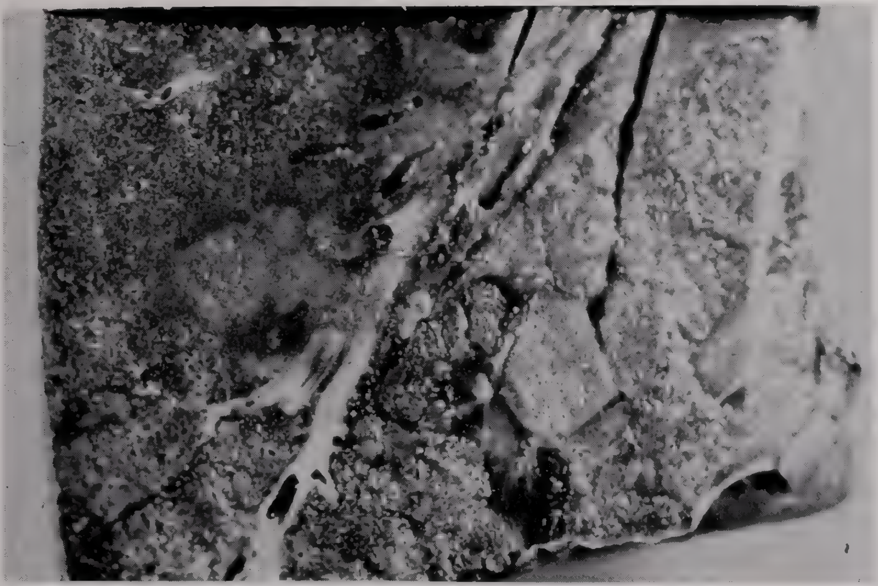

Fig. 5—Cut surface of lung with central zone of infarction due to fungal arteritis.

these areas revealed a fungal arteritis with branching septate hyphae suggesting infection with Aspergillus species. The thyroid gland was similarly infected with branching hyphae of Aspergillus species.

The liver revealed focal acute hepatic central congestion and atrophy without evidence of infection with salivary gland virus. The pancreatic substance similarly contained foci of necrosis, and examination of the acinar cells adjacent to the areas of necrosis failed to show evidence of cytomegalovirus. In other cases of our transplant series we have seen erosive processes and areas of necrosis in the pancreas, and I have ascribed this to the immunosuppressive therapy.

A few sharply punched-out, circumscribed ulcers were noted in the mucosa of the antrum of the stomach and considerable hemorrhage was present in the bowel lumen distal to the ligament of Treitz. A gram stain of the gastric

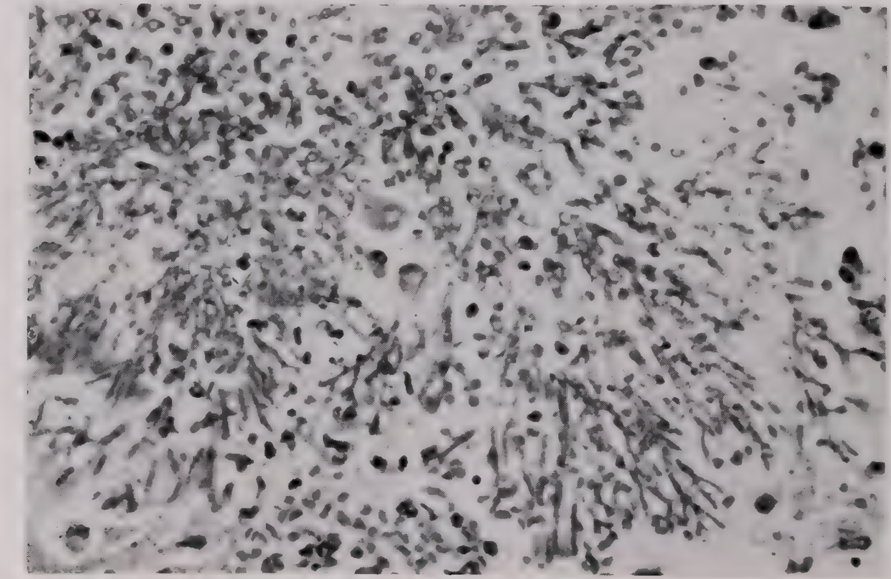

Fig. 6—400X Branching septate hyphae of Aspergillus fumigatus in section of lung tissue. Hematoxylin and Eosin.

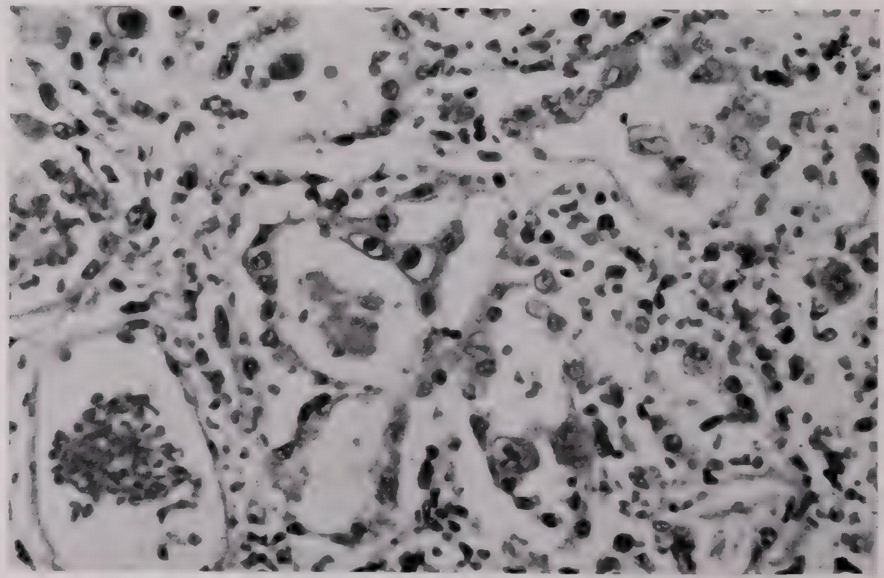

Fig. 7—400X Large red inclusion bodies of Cytomegalovirus in the nuclei of cells lining alveolar septae.

mucosa in these sites showed proliferating pseudomycelia of Candida albicans. In the series of patients with systemic candidiasis reported from the University of Colorado, the portal of entry of the Candida organisms was frequently the gastrointestinal tract.

The brain sections on this patient were very striking, showing multiple foci of hemorrhagic necrosis (Figure 8). Many of the zones of hemorrhage and necrosis occurred at the corticomedullary junction; these hemorrhages in regional infarcts are frequently present with an embolic infection of the central nervous system by Aspergillus fumigatus. Proliferating Aspergillus mycelia can be observed in vessels of the meninges confirming the presence of a mycotic meningitis. Some of the hemorrhagic zones in the brain abut on the leptomeninges, and up to 10 to 15% of a series of cases of Aspergillus infections of the central nervous system may be associated with fungal growth in the cerebrospinal fluid. On microscopic examination of the brain, one sees

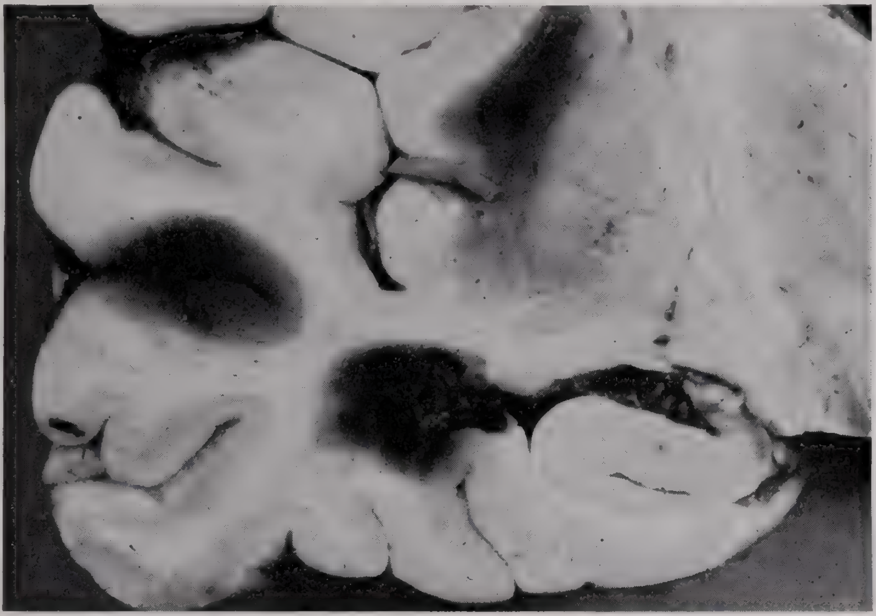

Fig. 8—Brain hemorrhages and infarction secondary to fungal arteritis caused by Aspergillus fumigatus.

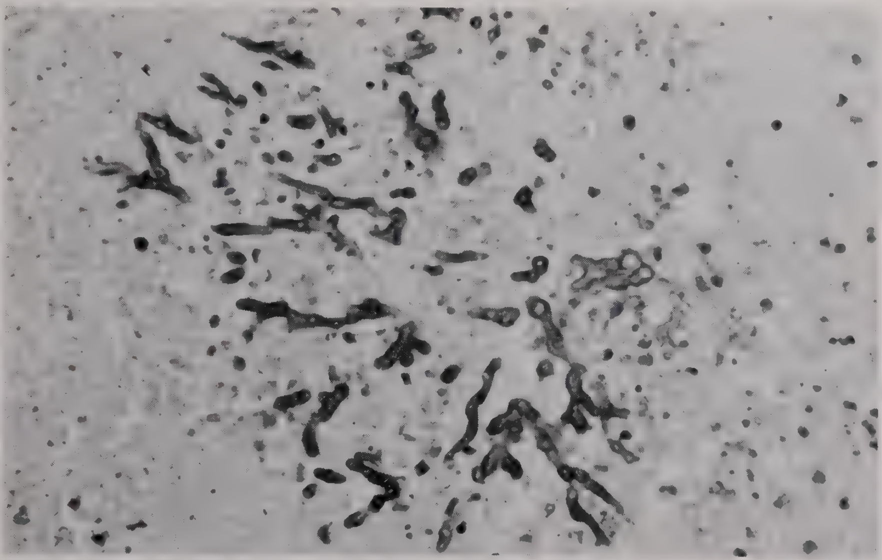

Fig. 9—400X Ray-like septate hyphae of Aspergillus fumigatus in brain tissue.

an active fungal arteritis with proliferating mycelia extending through the arterial walls and obstructing the lumen of vessels. Hemorrhagic infarctions are seen in the surrounding brain tissue and fungal mycelia in the brain substance itself. A PAS stain of the branching hyphae is confirmatory evidence that these are septate hyphae of Aspergillus species (Figure 9). On gram stains of the brain, one could see a mixture of gram-positive pseudomycelia and gram-negative branching true hyphae, suggesting that the nervous system was infected with both Candida and Aspergillus species.

Dr. George Kitzmiller:*

Do you need a special culture medium for isolation of Aspergillus species?

Dr. Strom:

No, that is not necessary; Aspergillus species grows extremely well on Sabouraud's agar or even human blood agar. Aspergillus species is a ubiquitous organism; it is carried by the ambient air in the bacteriology laboratory and may fall on our culture plates. The important thing to realize is that with this sort of problem you have to be suspicious of Aspergillus as a pathogen and ask for fungus cultures for Aspergillus on Sabouraud's medium. In this case, we did not grow the Aspergillus species from the lung or spinal fluid. In the University of Colorado series, they had difficulty isolating Aspergillus species from the sputum. Positive cultures of the fungal pathogen were isolated in only six out of 13 cases of fungus infection with pulmonary involvement.

University of Colorado Experience

I would like to comment further on the experience at the University of Colorado with opportunistic infections following renal transplantation.[3,4] Systemic fungus infection was found to be present in twenty-three of fifty-one patients who died following renal homotransplant for an incidence of 45%. The fungal agent causing the infection in twelve cases was Candida species, in five cases Aspergillus species, in two cases Nocardia species, in one case Histoplasma capsulatum, and in three instances combinations of the above infecting fungi. With regard to organ involvement by the systemic fungus infections, the pulmonary tract was involved in nineteen of the twenty-three patients who died of fungus infection. The gastrointestinal tract was involved in nine cases, the central nervous system in eight, the kidneys in four, and other organs in ten cases. The cases of Aspergillus infection showed a definite predilection for the central nervous system with five out of seven cases showing central nervous system involvement. Cases with systemic candidiasis showed a predilection for involvement of the gastrointestinal tract; in four of these cases, gastrointestinal tract involvement was present without lung involvement, suggesting an intestinal portal of entry.

Predisposing Factors

Those patients with systemic fungal infection after renal transplantation were slightly older than the average age group in the renal transplant deaths, and there was a striking male predominance, with twenty-two out of twenty-three cases of fungal infection occurring in males. The series with and without fungal infection showed no difference in dosage of immunosuppressive drugs or duration of antibiotic therapy. Sputum culture revealed the infecting fungus in six of fourteen patients for an incidence of 43%. Ante-mortem diagnosis and institution of treatment for systemic fungal infection occurred in only two patients. Concomitant bacterial, viral, or parasitic disease was present in 87% of patients. Included in this series were five cases of infection with pneumocystis carinii and thirteen instances of infection with cytomegalic inclusion virus. The incidence of cytomegalic inclusion virus infection in these patients was 57%: an extremely high incidence. There was an association between infections with pneumocystis carinii and high-dose steroid therapy. The majority of the cases of pneumocystosis were on high doses of steroids for over three months, whereas the systemic fungal infections occurred somewhat earlier. The systemic fungal infections developed on an average of sixty-seven days post transplantation; and after onset of clinical symptoms, the average time to death was 23 days.

---

*Staff physician, Hennepin County General Hospital.

Most of the cases of systemic candidiasis in the literature are associated with long-term antibiotic therapy and the portal of entry is frequently an indwelling polyethylene catheter or the gastrointestinal tract. This has been recognized particularly in association with the tetracycline group of drugs.

One of the paradoxes in the data from the University of Colorado is that the incidence of infection does not correlate with the dosage level or duration of therapy with immunosuppressive agents and antibiotics. Systemic fungal infections are seen with steroid therapy alone, but the combination of steroid therapy and immunosuppression appears to heighten the susceptibility of the patient to disseminated fungus infection. Similarly in experimental animals, pretreatment with steroids and immunosuppressive agents leads to a high incidence of systemic fungus infection. If you give the animals just the fungal agent without the associated antibiotics and immunosuppressive drugs, experimental infection is frequently not produced.

In summary, our case represents an opportunistic infection with multiple organisms following renal transplantation. Candida albicans and Aspergillus fumigatus were felt to have disseminated widely from the lung and the gastrointestinal tract with dissemination to the brain. An associated cytomegalic inclusion virus infection of the lungs was present.

Final Anatomic Diagnosis:

1. Systemic aspergillosis and candidiasis involving the lung, gastrointestinal tract, heart, thyroid, and brain.
2. Cytomegalic inclusion virus infection of the lungs.
3. Varicella-zoster virus infection of the skin.
4. Status post rejection of cadaveric renal homotransplant.

The reason why some people have their backs against the wall is that they've been keeping up a front.—Inez Ozburn

A high index of suspicion... E. coli

How high is the "index of suspicion" for *E. coli* in urinary tract infections?

Recently it has been estimated that about 86 per cent of positive cultures in first attacks of urinary tract infection are *E. coli.*[1] It has also been noted that "The coliform group, especially *E. coli*, accounts for approximately 90 per cent of initial infections...."[2]

Consider wide-spectrum Gantanol® (sulfamethoxazole) for its high "index of confidence"—its proven effectiveness against *E. coli* and other sensitive gram-negative and gram-positive organisms. Therapeutic levels of Gantanol in blood and urine are achieved within 2 hours after a 2-Gm starting dose, with ready diffusion into interstitial fluids. Responsive infections generally clear within 5 to 7 days, with relief of symptoms usually seen within 24-48 hours.

Gantanol also earns its high "index of confidence" because Gantanol therapy is relatively free from complications, including the problem of bacterial resistance or superinfection.

Convenient, economical dosage schedule: *b.i.d.*

References: 1. Vernier, R. L., in Patient Care Feature: *Patient Care, 1*:20 (Feb.) 1967. **2.** Beeson, P. B.: "The Infectious Diseases," in Beeson, P. B., and McDermott, W. (eds.): *Cecil-Loeb Textbook of Medicine*, ed. 12, Philadelphia, W. B. Saunders Company, 1967, p. 230.

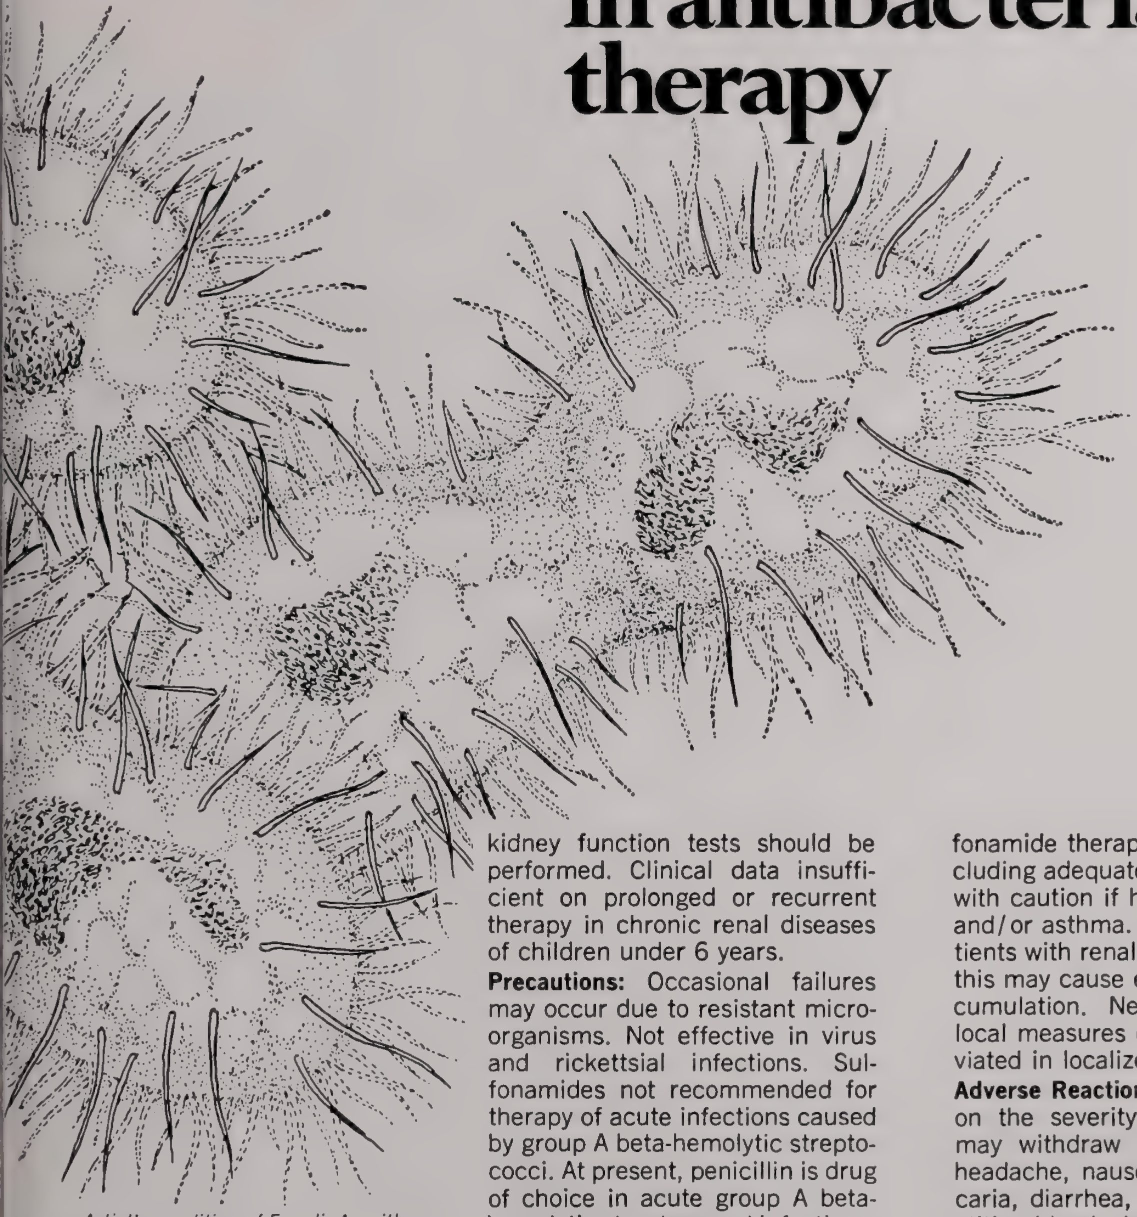
Before prescribing, please consult complete product information, a summary of which follows:

Indications: Acute and chronic urinary tract, respiratory and soft tissue infections due to susceptible microorganisms; prophylactically following diagnostic instrumental procedures on genitourinary tract.

Contraindicated in sulfonamide-sensitive patients, pregnant females at term, premature infants, or newborn infants during first 3 months of life.

Warnings: Use only after critical appraisal in patients with liver or renal damage, urinary obstruction or blood dyscrasias. Deaths reported from hypersensitivity reactions, Stevens-Johnson syndrome, agranulocytosis, aplastic anemia and other blood dyscrasias. In closely intermittent or prolonged therapy, blood counts and liver and

For a high index of confidence... Gantanol® (sulfamethoxazole) in antibacterial therapy



Artist's rendition of E. coli. As with most strains of E. coli, these have flagella and are motile.

kidney function tests should be performed. Clinical data insufficient on prolonged or recurrent therapy in chronic renal diseases of children under 6 years.

Precautions: Occasional failures may occur due to resistant microorganisms. Not effective in virus and rickettsial infections. Sulfonamides not recommended for therapy of acute infections caused by group A beta-hemolytic streptococci. At present, penicillin is drug of choice in acute group A beta-hemolytic streptococcal infections; although Gantanol has produced favorable bacteriologic conversion rates in this infection, data insufficient on long-term follow-up studies as to its effect on sequelae of rheumatic fever or acute glomerulonephritis. If other treatment cannot be used and Gantanol is employed in such infections, *important that therapy be continued in usual recommended dosage for at least 10 days*. Observe usual sulfonamide therapy precautions, including adequate fluid intake. Use with caution if history of allergies and/or asthma. Follow closely patients with renal impairment since this may cause excessive drug accumulation. Need for indicated local measures or surgery not obviated in localized infections.

Adverse Reactions: Depending upon the severity of the reaction, may withdraw drug in event of headache, nausea, vomiting, urticaria, diarrhea, hepatitis, pancreatitis, blood dyscrasias, neuropathy, drug fever, Stevens-Johnson syndrome, skin rash, injection of the conjunctiva and sclera, petechiae, purpura, hematuria and crystalluria.

in cerebrovascular disorders

Arlidin increases blood flow

Arlidin decreases cerebral vascular resistance, increases cardiac output, helps maintain mean arterial pressure.

Arlidin helps control vasoconstriction, vasospasm, and ischemia.

Arlidin may thus relieve symptoms of cerebrovascular insufficiency, such as vertigo, lightheadedness, and mental confusion.

Arlidin also increases blood flow to the eye and inner ear to help manage ischemic disorders of those organs.

Arlidin is well tolerated and relatively free of severe adverse reactions.

DOSAGE: Usual effective dosage ½ to 1 tablet t.i.d. or q.i.d.; increased, if necessary, to 2 tablets t.i.d. or q.i.d. Parenterally, 0.5 cc. by subcutaneous or intramuscular injection; increased gradually to 1 cc. one or more times daily, as needed. SIDE EFFECT: Occasional palpitation. PRECAUTIONS: Use with caution in the presence of a recent myocardial lesion, paroxysmal tachycardia, severe angina pectoris, thyrotoxicosis. CONTRAINDICATION: Acute myocardial infarction. SUPPLIED: Tablets, 6 mg., scored; bottles of 100 and 1000. Parenteral, 5 mg. per cc., 1 cc. ampuls (5 per box); 10 cc. multiple-dose vials (1 per box). CONSULT PRODUCT BROCHURE.

ARLIDIN®
brand of
NYLIDRIN HCl

INCREASES
BLOOD
FLOW

DECREASES
ARTERIAL
RESISTANCE

For elderly patients
in need of a mild tranquilizer
consider **Tybatran®**
brand of tybamate

(When you consult
the Prescribing Information
you may agree
it makes good sense)

PRESCRIBING INFORMATION

Indications: Tybatran (tybamate) has afforded symptomatic improvement in a variety of psychoneurotic disorders, especially in the treatment of the anxiety and tension components of psychoneuroses. Anxiety states manifested somatically have responded to Tybatran (tybamate).

Tybatran (tybamate) has been useful in the control of agitation in the aged and in the alleviation of some of the adverse emotional accompaniments of senility.

Tybatran (tybamate) has been used with benefit in the treatment of depressive symptoms associated with anxiety and other symptoms of psychoneuroses. However, it is not indicated for primary treatment of depressive states. It is not an antipsychotic agent, although it has been used as adjunctive therapy in some psychotic patients.

Dosage: One 350 mg. capsule, 3 times daily and two at bedtime is suggested as the adult starting dose. Adjust to suit individual requirements. Daily doses above 3000 mg. are not recommended.

Contraindications: Known hypersensitivity to tybamate. Since no studies have been done with this drug in human pregnancy, it should not be used in pregnancy unless the potential benefit outweighs the risk.

Warnings: Administer cautiously to patients receiving phenothiazines or other CNS depressants or having history of convulsive seizures (See Adverse Reactions). Consider possibility of additive actions with alcohol or other psychotropic agents, particularly phenothiazines or MAO inhibitors.

Precautions: Avoid abrupt withdrawal after prolonged use, although withdrawal symptoms have not been reported to date. Exercise caution in addiction-prone individuals. If symptoms of hypersensitivity occur, discontinue at once and initiate appropriate symptomatic treatment. Avoid activities requiring optimal mental alertness if drowsiness or vertigo are present. As with any new drug, use cautiously in patients with history of drug allergies, blood dyscrasias, and hepatic or renal disease; periodic measurements of hepatic, hematopoietic and renal function should accompany prolonged and/or high doses.

Adverse Reactions: Most frequent reactions, rarely requiring discontinuation of tybamate, include drowsiness, dizziness, nausea, insomnia, and euphoria. There have been a few reports of skin rash, urticaria, and pruritus. Rare side effects include hyperactivity, fidgetiness, flushing, and tachycardia, suggesting excessive stimulation; also ataxia, unsteadiness, confusion, feeling of unreality, "panic reaction," fatigue, headache, paresthesias, vertigo, gastrointestinal disturbances, glossitis, and dry mouth. Grand mal or petit mal seizures have been reported in a few hospitalized psychotic patients receiving tybamate (up to 6000 mg. daily) together with phenothiazines and other psychotropic agents, but not with tybamate alone. Consider the possibility of rare, serious adverse reactions such as may occur with the related drug, meprobamate. If excessive amounts are ingested, gastric lavage and symptomatic therapy, including central stimulants as necessary, are recommended. Before prescribing, consult package circular.

Supply: Tybatran (tybamate) is available in green, sealed capsules of three strengths: 350 mg., 250 mg., and 125 mg. Each strength is supplied in bottles of 100 and 500.

PSYCHIATRIC RESIDENCIES: We offer nothing but excellent psychiatric training in a stimulating, well organized program located in a culturally advantaged community. Approved psychiatric training. Traverse City State Hospital, Michigan Department of Mental Health. Three and five year programs. Salary, 3 year program: $10,669; $11,191; $12,131. 5 year program: $12,152; $14,031; $16,328. $21,944; $23,093. NIMH-GP stipends available. Located in Michigan's serene, scenic recreation area on Grand Traverse Bay. Contact Dr. Paul E. Kauffman, Director of Training, Traverse City State Hospital, Traverse City, Michigan 49684. An equal opportunity employer.

WANTED: G.P. to join clinic serving population area of 12,000. City has new hospital, new clinic building, two nursing homes, new Jr-Sr high school, new swimming pool, rich farming area. Fishing and hunting nearby; metropolitan city close by. Salary open and partnership if interested. Write: MINNESOTA MEDICINE-423, 375 Jackson, St. Paul 55101.

GENERAL PRACTITIONER WANTED to join well-established three man group in Twin City area. Starting salary $20,000.00 to $25,000.00 range with opportunity for early partnership; or, will negotiate. Write: MINNESOTA MEDICINE-424, 375 Jackson, St. Paul 55101.

TEN MAN MULTISPECIALTY group needs an ophthalmologist and another pediatrician. New clinic building, complete laboratory and x-ray facilities. 180 bed modern hospital across street from clinic. Early share-holder status. Salary open. Write or call the Lenont-Peterson Clinic, Ltd., C. A. Tietz, M.D., area code 218, 741-4292, Virginia, Minnesota 55792.

WANTED: Young physician for association leading to partnership with four well established General Practitioners in fast growing suburb of St. Paul. Excellent clinic facilities in nearly new, partnership owned, well equipped, medical center building. Write: MINNESOTA MEDICINE-421, 375 Jackson, St. Paul 55101.

DIRECTOR OF HOUSE SERVICE—An ideal position for someone in family practice who wants a less strenuous life in a stimulating medical environment. Excellent annual fee, plus fringe benefits. Located in Minneapolis, known nationally as an ideal city for family living. Every possible professional, educational, cultural and recreational opportunity. Teams in all major league sports. Write of your interest and come for an expense-paid visit. Write: MINNESOTA MEDICINE-422, 375 Jackson, St. Paul 55101.

GENERAL SURGEON: Board certified or eligible. 269 bed General Medical and Surgical Hospital in Michigan's Upper Peninsula. Licensure any state, salary dependent upon background and qualifications. Excellent benefits for retirement, vacations, sick leave, and professional improvements. Non-discrimination in employment. Contact Chief of Staff, VA Hospital, Iron Mountain, Michigan 49801.

GENERAL PRACTITIONER wanted to join well-established practitioner. New clinic building—90 miles east of St. Paul—city of 14,000. Early partnership with full hospital facilities. Ideal location. L. W. Picotte, M.D.; Chippewa Falls, Wisconsin.

Advance

Candidiasis: Systemic and Disseminated

THE SIGNIFICANCE of isolating strains of *Candida* in a given case is often difficult to establish, because these organisms may be members of the normal body flora. Also *Candida* organisms may be isolated as contaminants in other diseases, as when they are found in the sputa of patients with known pulmonary disease, such as tuberculosis and carcinoma.[1] Before the era of modern therapy, patients with extensive visceral involvement due to *Candida* species were seen only occasionally. With the introduction of currently available drugs and therapeutic procedures, instances of such candidal infections occur with increasing frequency.

Advances in knowledge of the pathogenesis, clinical manifestations and management of candidiasis are being made. Herein is an attempt to summarize this knowledge from the point of view of the practitioner-internist.

Clinical Syndromes

In patients with localized candidiasis, such as oral, cutaneous, or vaginal infection, systemic disease may occur spontaneously but is more likely to be encountered in persons who have underlying diseases or those receiving predisposing therapies. In this presentation, systemic candidiasis refers to infection that predominantly involves one body system and is characterized by a constitutional reaction. Disseminated candidiasis, which refers to multisystem disease, may result from extension of either localized or systemic infection.

Systemic Candidiasis

Candidemia-fungemia due to *Candida* species is suggestive of disseminated disease or seeding of the bloodstream from a focus of significant visceral infection. However, in a number of cases, candidemia represents transient invasion of the blood, the elimination of which does not require systemic therapy. In other words, *Candida* may be cultured from the blood, but the subsequent clinical course of the patient, or the postmortem examination, indicates that established infection was not present.[2] In these cases, the transient fungemia may reflect such things as an infected intravenous catheter or antibiotic-induced floral changes with candidal overgrowth.

In patients who have persistent fungemia, especially those who have serious underlying disease, are receiving predisposing drugs, or have intravenous or indwelling urinary catheters, their clinical deterioration is the usual stimulus to consideration of therapy with amphotericin B. In some instances of persistent candidemia, examination of the patient's urine may reveal the pathogen before blood and urine cultures are reported. Because negative blood cultures have been noted in patients with disseminated candidiasis, the urine should be examined simultaneously for the presence of *Candida* in such cases. Because the kidney is the organ of maximal involvement in disseminated candidiasis, significant candiduria is not unexpected.[3,4]

Candidal Endocarditis—Approximately 75% of patients with endocarditis due to *Candida* species, unassociated with cardiovascular surgery, are believed to have preexisting valvular damage. Dick and Mullin[5] described a patient in whom the fungus was localized to the surface of an atrial myxoma. Candidal endocarditis after cardiovascular surgery has been rising steadily in incidence in recent years. The infection appears to be related to intravenous injections in most cases, but there is the possibility of direct access by the organisms to the heart valves at the time of cardiac surgery. Prior antimicrobial therapy and the trauma of cardiopulmonary bypass may be significant factors in the genesis of the infection. Although most instances of systemic and disseminated candidasis are caused by *C. albicans,* endocarditis in about half of the instances has been due to other strains of *Candida.*[6] The clinical manifestations of candidal endocarditis are usually similar to those of bacterial endocarditis, except for the more frequent occurrence of major embolic phenomena.

Such emboli have been reported in about 50% of cases and may reflect the characteristically large vegetations found at autopsy, which may have an area of as much as 5 cm. In some cases protracted, unexplained fever is the only consistent clinical finding. Petechiae and splenomegaly are usual. Blood cultures are not consistently positive in all cases. Candiduria and azotemia are infrequent. During treatment with amphotericin B, the infecting organism may grow in culture medium of hypertonic blood when there is no growth in ordinary blood cultures.[7,8] In one such case, small, beadlike, friable vegetations were found at operation instead of the larger vegetations commonly encountered in endocardial candidiasis.[8] Amphotericin B (Fungizone) is generally considered to be ineffective in the presence of an intravascular prosthesis, and it is recommended that the prosthesis be replaced if it is considered to be a focus of fungemia. In cases of refractory candidal endocarditis occurring in patients without such a prosthesis, it is also worthwhile to consider surgical intervention and removal of the valvular nidus of infection or even replacement of the valve.

Gastrointestinal Candidiasis — Candidal infections of the mouth not uncommonly spread to directly involve the pharynx, larynx, and esophagus.[9] Death from systemic candidiasis has been noted after dental surgery. Thrush in infants may be acquired in an epidemic fashion in the nursery, much like staphylococcal infections; it may also occur via the mother.[9] The usual treatment of this variant of the infection is to attempt to maintain concentrations of nystatin (Mycostatin) in the mouth, pharynx, and esophagus. However, in advanced disease, therapy with amphotericin B may be required.

Candidal esophagitis has occurred in the absence of candidiasis of the oral cavity. Retrosternal pain on swallowing, especially in patients receiving predisposing drugs, should bring this possible complication to mind. Characteristically, the barium-filled esophagus demonstrates lack of motility, decreased distensibility, increased retention of the contrast medium on the mucosal surface, and highly variable filling defects. In patients with candidal esophagitis, esophagoscopy may be dangerous because of the possibility of perforation.[10] The organism may be cultured from gastric aspirate and stool. Examples of gastric and duodenal candidiasis have also been observed.[3]

Because *Candida* organisms are part of the normal flora of the gastrointestinal tract, their presence in cultures of the stool may be difficult to interpret. However, in patients having certain underlying illnesses and receiving predisposing therapies, increased numbers of these organisms may provoke gastrointestinal irritation, usually in the form of diarrhea. Such a gastrointestinal focus may lead to significant fungemia. Especially in obese diabetics, overgrowing *Candida* may spread externally to involve the perineum and groin. Rectal candidiasis also has been observed.[3]

Pulmonary Candidiasis — Primary pulmonary candidiasis is rare, but the incidence of infection secondary to underlying diseases is reported to be increasing.[11] Pulmonary candidiasis may present as a mild recurrent bronchopulmonary infection with persistent and productive cough. Examination of the sputum reveals the presence of large numbers of budding yeast cells and pseudomycelia. Other patients may have more severe infection, and roentgenograms of the thorax may indicate consolidation and pleural reaction. Still other patients may demonstrate a miliary type of pulmonary infiltration and have associated fungemia. A definite diagnosis can be made by obtaining repeatedly positive cultures from bronchoscopic washings, by simultaneously culturing the organism from pleural fluid or blood, or by demonstrating *Candida* in biopsy sections of the lung. In disseminated candidiasis, the lungs are often involved, but the kidneys usually are the sites of maximal infection. When a diagnosis of pulmonary candidiasis has been established, the use of predisposing drugs such as antibiotics should be discontinued. With candidal bronchitis, no other therapy may be needed; if pneumonia is present, specific therapy will be necessary. Aerosolization of nystatin has been recommended in persistent milder infections.[12] Amphotericin B is required in more severe infections.

Genitourinary Candidiasis — Candidal invasion of the urinary tract is not infrequent in patients having underlying disease and receiving antibacterial therapy. In most instances of this variety, removal of the urinary catheter and cessation of antibacterial therapy are sufficient to halt the invasion. Of course, on occasion, such invasion is complicated by fungemia and even disseminated candidiasis. In disseminated disease, of whatever portal, the kidneys usually become the site of maximal infection. The concept has evolved that the tubular lumen provides a protected site for growth of the *Candida*, and evasion by the organisms of host defenses may be significant in the establishment of progressive renal infection.[3] In patients who are suspected of having disseminated disease, the urine, as well as the blood, should be cultured. Careful examination of the urinary sediment for yeasts may be diagnostic before reports of cultures become available.

Candidal balanitis and urethritis in the male have been reported. Treatment of the sexual partner may be required to prevent continued or recurrent infection.[9]

Candidal vulvovaginitis occurs when *Candida* species overgrow the vagina's normal bacteria, especially in diabetic women, pregnant women, and those receiving predisposing drugs. Among several forms of effective therapy, intravaginal use of nystatin, candicidin, or nifuroxime daily for two weeks or longer is usually successful. Vulvovaginitis associated with the use of oral contraceptives may not yield to treatment unless the use of "the pill" is discontinued.[13]

Intra-uterine infection of the fetus by candidal organisms, with resulting systemic candidiasis in the infant, has been reported by several investigators.[14-16] Although intrapartum contamination leading to cutaneous candidiasis is common, systemic infection in the infant is rare. A case of congenital systemic candidiasis is reported[16] in which the infant was born by cesarean section without prior rupture of the amniotic membranes. The route of infection is postulated to be either ascension of *Candida* from the mother's vagina and contamination of the amniotic fluid or hematogenous spread to the infant from the maternal focus. Cultures from multiple sites in the infant grow the organisms, with the lungs and kidneys being maximally involved.

Candidiasis of the Soft Tissues, Skeleton, and Central Nervous System—Postoperative wound infection due to *Candida* species has been complicated by candidemia.[2] Candidal cellulitis has been similarly complicated.[3] Candidal abscesses of multiple sites in the body, including the soft tissues, occur, but are usually encountered in patients with disseminated disease.

Candidal osteomyelitis may occur in patients with localized candidiasis elsewhere in the body.[17] Skeletal infections also may be noted in patients with disseminated candidiasis.

Both candidal meningitis and brain abscess have been encountered in patients without underlying disease and to whom predisposing drugs were not being administered. However, the increasing incidence of candidal infections of the central nervous system is undoubtedly related to underlying diseases and the use of predisposing drugs. An area of localized candidiasis elsewhere in the body, such as the skin or gastrointestinal tract, can be demonstrated in at least 50% of patients. Fever, headache, and vomiting are common presenting manifestations. Diplopia is not uncommon. Papilledema is frequent, and most patients have stiffness of the neck. More than one third have focal neurologic signs. In almost one half of the cases, *Candida* organisms are noted on direct examination of the spinal fluid. At autopsy, in about one third of the cases, visceral lesions, usually involving the kidneys, are found. In addition to amphotericin B therapy, drainage of brain abscesses is required.

Disseminated Candidiasis

Bogen and Kessel[18] reported the first case of disseminated candidiasis in an adult in 1937. Louria and co-workers[3] collected an additional 31 cases in persons more than 10 years old and pointed out that most of these cases have been encountered in the antibiotic-adrenal hormone era. Only about 20% of patients have disseminated candidiasis without having received prior antibiotic or corticosteroid therapy. Dissemination may occur in patients with localized areas of candidiasis in the gastrointestinal tract, skeleton, lungs, and other body sites. Disseminated candidiasis has occurred after dental extraction. At autopsy, the renal tissue is the site of maximal infection and abscesses may involve multiple regions, including the myocardium, brain, and lung. In this variant of the infection, the esophagus is the most frequently involved portion of the gastrointestinal tract, but gastric, duodenal, colon, and rectal involvement occurs.

Patients, Pathogens, and Portals

Patients afflicted with certain underlying diseases or conditions are particularly susceptible to systemic and disseminated candidiasis. These diseases and conditions include diabetes mellitus, hematopoietic disorders such as leukemia, malignancy, lupus erythematosus, rheumatoid arthritis, Cushing's disease, alcoholism, cirrhosis, severe burns, pulmonary alveolar proteinosis, uremia, malnutrition, postoperative states, pregnancy, hypocalcemia, Addison's disease, and certain states characterized by deficiencies in the gamma-globulins.

Patients receiving antibiotics appear to become more susceptible to candidiasis because of the suppressive effect of these drugs on members of the normal body flora, thus allowing overgrowth of other organisms including *Candida*. Adrenal corticosteroids so alter host defenses that patients receiving them also have increased susceptibility to candidal invasion. Use of radiomimetic drugs, immunosuppressive therapy, radiation, and surgical procedures also appear to decrease host resistance and enhance the likelihood of candidiasis.

Infections in man caused by species of *Candida* are usually due to *C. albicans*. *C. tropicalis* also produces systemic infection in man. Other members of the genus include *C. parapsilosis, C. pseudotropicalis, C. krusei, C. guilliermondi*, and *C. stellatoidea*. Excepting candidal endocarditis, these latter organisms rarely cause systemic or disseminated disease in man. About one half of the cases of candidal endocarditis are caused by members of the genus other than *C. albicans; C. albicans, C. parapsilosis*, and *C. guilliermondi* are the three organisms most commonly responsible for candidal endocarditis.

Preexisting mucocutaneous, gastrointestinal, and genitourinary candidiasis can be complicated by systemic or disseminated disease, especially if a precipitating factor, such as use of a predisposing drug, is supplied. The *Candida* may have direct access to the bloodstream through *prolonged use of intravascular catheters;* substitution of so-called scalp-vein needles may reduce the incidence of candidal infection via this portal. Frequent intravenous injections may provide a similar mechanism, and this is commonly operative in narcotic addicts in whom candidal endocarditis develops. Direct access to the heart valves at cardiac surgery may allow candidal implantation; the trauma of the operation and employment of cardiopulmonary bypass may enhance the likelihood of candidal endocarditis. An indwelling urinary catheter may likewise increase the possibility of candidiasis resulting from that portal. Rupture of a viscus, such as perforated diverticulitis coli may also result in systemic or disseminated infection. Surgical interruption of the gastrointestinal mucosa may eventuate in a similar chain of events.[3]

Clinical and Laboratory Findings: Some Generalizations

Fever is usual and characteristically remittent, and temperatures (oral) may range from 101 to 105 F. Shaking chills are noted in about 25% of patients, especially at the onset of fungemia.

A shock-like syndrome characterized by hypotension and oliguria occurs in about one third of patients at the time of fungemia.[3,19]

Petechiae and embolic phenomena, in the absence of candidal endocarditis, are uncommon in candidiasis.

Tachycardia and tachypnea are common but appear to be of no prognostic significance.[3]

In patients without underlying hematopoietic disease, leukocytosis and neutrophilia are usual. A normocytic normochromic anemia occurs in most patients.

Candida cells, if seen in the urinary sediment, may be diagnostic before the report of cultural data. Azotemia of variable degree occurs in about 50% of patients who do not have intrinsic renal disease at the onset of the infection. Of these patients, if therapy is unsuccessful, two thirds will have extensive renal candidiasis at autopsy. However, candiduria and azotemia are infrequent in candidal endocarditis.

In addition to the urinary sediment, other sources such as sputum or material from oral lesions and body fluids, when placed in a drop of 10% solution of potassium hydroxide under a cover glass and gently heated, may reveal the fungus.

It is to be stressed that isolation of *Candida* species does not per se indicate that the organism is necessarily causing disease. Such isolation may indicate either contamination from an exogenous source or habitation within the body in a commensal relationship without tissue invasion. Repeated isolation of the organism, or demonstration of it in tissue obtained by biopsy or autopsy, is a more exact basis for implicating the organism to be pathogenic. Isolation of *Candida* organisms from aspirates of closed-space infections such as abscesses or empyema, or from specimens of blood, urine, or spinal fluid more likely indicates significant infection. Pseudomycelia, especially their predominance over yeast forms on a smear preparation, may be more reliable evidence of infection than the presence of yeast forms alone. Examination of the buffy coat of a blood sample may reveal intracellular yeast forms and be helpful in the diagnosis of candidiasis, especially in patients in whom blood cultures are negative.[11]

Some Therapeutic Considerations

Antibiotic

The keystone of management of systemic and disseminated candidiasis is *amphotericin B*.[20-22] Although the mortality rate in patients with severe disease remains high, and despite the considerable toxicity of amphotericin B, it is the only effective and commercially available antimycotic agent having systemic effect. Patients with endocarditis, meningitis, or severe pyelonephritis are less likely to respond to therapy. In less severe infections, 25 to 50 mg of amphotericin B given each day intravenously for seven to 14 days may suffice. In more severe infections, higher daily doses should be given if the patient can tolerate them, and treatment should be continued four to six weeks.

Intrathecal or intraventricular administration of amphotericin B should be considered in patients with meningitis. Injection of the drug into other body cavities, such as the pleural space in patients having empyema, may have application. Amphotericin B has been given as an aerosol, applied to cutaneous and mucosal lesions, and injected directly into subcutaneous tumefactions and regions of osteomyelitis. It also has been given via arterial perfusion into an isolated limb and has been introduced into the lungs via endobronchial catheter.

Amphotericin B may be curative in candidal endocarditis that complicates cardiac operations. However, because the presence of foreign bodies (sutures, prostheses) may be implicated in the genesis of the lesion, cardiotomy with excision of vegetations and repair of any defect also is probably required. As noted previously, in endocarditis, unassociated with a prosthesis, surgical intervention and perhaps valvular replacement also may be considered.

Change Therapy

It is important to recall that infection, including fungemia, in some instances will resolve by change of intravenous tubing, removal of catheters or needles, discontinuance of predisposing drugs, and control of underlying diseases or conditions. Attention should be directed toward control of underlying diseases or conditions because the pathogenesis of systemic and disseminated candidiasis is intimately related to alterations in host resistance. Stringent efforts should be made to control malignancies, to correct malnutrition, to ameliorate blood dyscrasias, and to regulate diabetes mellitus and the like. The indications for such regimens as the glucocorticoids, cytotoxic agents, immunosuppressive drugs, antibiotics, and roentgen therapy should be reevaluated. Nonessential therapy should be discontinued, and other medications should be administered in the lowest dosage that is effective. Supportive measures including rest, improved nutrition, general hygiene, and care of the skin and mucous membranes are not to be neglected.

Surgical

Surgical intervention in nonendocardial candidiasis may also be an important adjunct. All foci of dead and devitalized tissues, sinus tracts, and fistulas should receive surgical consideration. Abscesses, empyema, and regions of osteomyelitis should be drained. Chronic pulmonary lesions may require resection.

Chemotherapy

Nystatin is employed for local effect against infections due to *Candida* species; the drug is poorly absorbed from the gastrointestinal tract. Treatment of candidiasis of the gastrointestinal tract, vagina, and infected cut-down sites has been successful. Oral and topical forms may be used adjunctively in the management of certain patients, if auto-reinfection from the intestinal tract seems likely. Although there is no indication that nystatin need be employed in the average patient receiving antibiotics, oral administration of the drug in an attempt to reduce the number of these organisms in patients with such diseases as diabetes mellitus, malignancies, and hematopoietic disorders may be acceptable.

The usual oral dose of nystatin is 150 to 300 mg (500,000 to 1,000,000 units) three times daily. In candidiasis of the mouth, pharynx, and esophagus, one tablet of nystatin (500,000 units) dissolved in the mouth four times daily is recommended. In milder pulmonary infections, a suspension of nystatin (50,000 units) in 40% propylene glycol in normal sodium chloride solution given as an aerosol in divided daily doses has been effective.[12] Use of nystatin vaginal tablets or suppositories containing 100,000 units once or twice daily is recommended in cases of vaginal candidiasis. For local use, a vehicle containing 100,000 units per gram is applied to the area once to several times daily.

Candicidin (Candeptin) is an antibiotic that is effective topically in cases of vaginitis. One tablet (3 mg) of candicidin or one applicator full (3 mg) of ointment is inserted high into the vagina twice daily, in the morning and at bedtime, for 14 days.

There are two nitrofurans that have antimycotic activity. A nitrofurfuryl methyl ether (Furaspor) is used topically. Nifuroxime (Micofur) is a fungicide that is combined with furazolidone in the preparation Tricofuron. Vaginal suppositories of Tricofuron are used once or twice daily until the *Candida* organisms are eradicated, when therapy is discontinued after an additional seven to 14 days. In addition, vaginal insufflation of the drugs in powder form may be carried out once or twice weekly, depending on the case.

Comment

Opportunistic candidal infections are increasing in incidence, reflecting the increased number of patients with impaired ability to resist candidal invasion, due to underlying disease, use of certain drugs, or employment of various therapeutic procedures. Physicians must be aware of the vagaries of systemic and disseminated candidiasis in order to initiate appropriate diagnostic procedures. Identification depends largely on sending pertinent material for microbiologic examination. Identification is mandatory, because effective therapy including amphotericin B, surgery, and control of the underlying disease can eradicate a significant number of opportunistic candidal infections.

There are selected patients in whom the possibility of systemic or disseminated candidiasis should come to mind, especially if clinical deterioration supervenes without more obvious cause. These include patients with a known locus of infection, such as gastrointestinal or genitourinary candidiasis. In such patients, a malignancy, hematopoietic disorder, cirrhosis, or a similar disorder that may impair host resistance can enhance the likelihood of extrafocal candidal invasion, further encouraged by use of venous or urinary catheters, surgery, antibiotics, glucocorticoids, radiomimetic drugs, and similar therapies that disturb the equilibrium between victim and invader.

In many patients harboring *Candida* species, the organisms represent an incidental finding and are of no critical significance in the course of the illness. In some, however, the organisms may be responsible for clinical deterioration. In some patients, candidal infection, including fungemia, will subside on use of such measures as a change in intravenous tubing, removal of a urethral catheter, or decreasing or discontinuing predisposing regimens. In other patients, heroic therapy, the keystone of which is amphotericin B, is required to eradicate the infection. Careful evaluation of the individual situation is the best approach to the dilemma of not advising unnecessary antimycotic therapy on the one hand and, on the other, avoiding failure to administer such therapy in patients with significant infection.

Keeping Informed

One thing that is really not difficult, friends,
Is keeping abreast of new medical trends,
New treatments, new gadgets, new antibiotics,
New cures for the ailing, including neurotics.
And if you don't learn from attending a meeting
Or glancing at journals, though glances be fleeting,
Or talking with colleagues, you'll not be without it,
For surely your patient has read all about it.*

But before you prescribe Pertofrane, please see the full prescribing information and especially note Contraindications, Precautions, Warning, Adverse Reactions and Dosage. A brief summary of that information is included here.

Pertofrane® desipramine hydrochloride

Indications: For relief of depression.
Contraindications: Do not use drugs of the M.A.O.I. class with Pertofrane. Hyperpyretic crises or severe convulsive seizures may occur; potentiation of adverse effects can be serious or even fatal. When substituting this drug in patients receiving an M.A.O.I., allow an interval of at least 7 days. Initial dosage in such patients should be low and increases should be gradual and cautiously prescribed.
Warning: Activation of psychosis may occasionally be observed in schizophrenic patients. Do not use in patients under 12 years old, and do not use in women who are or may become pregnant unless the clinical situation warrants the potential risk.
Precautions: Careful supervision and protective measures for potentially suicidal patients are necessary. Discontinuation of therapy or adjunctive use of a sedative or tranquilizer may be necessary in the presence of increased anxiety or agitation, hypomania or manic excitement. However, phenothiazines may aggravate the condition. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those receiving anticholinergic drugs (including antiparkinsonism agents). Carefully observe patients with increased intraocular pressure. Prescribe cautiously in hyperthyroid patients and in those receiving thyroid medications. Cardiovascular complications (myocardial infarction and arrhythmias) are potential risks since they have occasionally occurred with imipramine, the parent compound. Desipramine may block the pharmacologic activity of guanethidine and related adrenergic neuron-blocking agents. Hypertensive episodes have been observed during surgery in patients on desipramine therapy.
Before prescribing the drug, the physician should be thoroughly familiar with prescribing information, with the literature, with all adverse reactions, with the diagnosis and management of depression, and with the relative merits of all measures for treating the condition.
Adverse Reactions: Dry mouth, constipation, disturbed visual accommodation, anorexia, perspiration, insomnia, drowsiness, dizziness, headache, nausea, epigastric distress, and skin rash (including photosensitization) may appear. Since orthostatic hypotension has occurred, carefully observe patients requiring concomitant vasodilating therapy, particularly during the initial phases. Other adverse reactions include tachycardia, changes in EEG patterns, tremor, falling, mild extrapyramidal activity, neuromuscular incoordination, epileptiform seizures. A confusional state (with such symptoms as hallucinations and disorientation) occurs occasionally and may require reduced dosage or discontinuance of therapy. Rarely, transient eosinophilia, slight elevation in transaminase levels, transient jaundice, or liver damage have occurred. If abnormalities occur in liver function tests, discontinue drug and investigate. Occasional hormonal effects, particularly decreased libido or impotence and instances of gynecomastia, galactorrhea and female breast enlargement have been observed. Urinary frequency or retention may occur. The drug should be discontinued if agranulocytosis, bone marrow depression, jaundice, thrombocytopenia, or purpura occur.
Dosage: 25 to 50 mg. t.i.d. The maximum daily dose is 200 mg. Continue maintenance dosage for at least 2 months after obtaining satisfactory response. Generally, elderly and adolescent patients should be given low doses.
Availability: Pink capsules of 25 mg. in bottles of 100 and 1000 (B) 46-530-E

For complete details, please see the prescribing information.

What makes a

A man?
Another woman?
Three kids?
No kids at all?
Wrinkles?
You name it.

Is she truly depressed?

Is that why she lets go
in your office?

You comfort her.
Talk to her.
And, if she is depressed,
consider Pertofrane.
Because
in 3 to 5 days
she can often begin
to cope,
work,
maybe play,
even enjoy.

Pertofrane®

desipramine hydrochloride
In depression…
when words are not enough

woman cry?

ASSOCIATE urgently needed in busy general practice. Excellent clinic and hospital facilities. Salary open. Partnership after 1 year. Klefstad Clinic, Greenbush, Minn. Call collect: Lloyd H. Klefstad, M.D., Tele. 218—782-5275 or 4725.

WANTED: G.P. for one year Locum Tenens or permanent practice in a friendly, relaxed, medically progressive community in northern Minnesota. Summer and winter recreation excellent; liberal salary & ample time off. Early partnership if desired. Start July 1, 1969 or sooner if desired. Contact Doctors Brende and McQuoid, Littlefork, Minn. 56653 or call collect 218-278-6651.

THREE MAN group in North West Wisconsin Resort, State Conservation and Retirement Area needs two more physicians adequately to serve their practice. Facilities offered are three-room physician suites, X-ray and lab under AMT technician, RN-only nursing personnel. New accredited thirty-two bed hospital and forty-six bed nursing home. Deer and duck hunting, fishing within five minutes of town. Internist most needed; generalists welcomed. Will meet any reasonable salary request. Partnership after one year. Write: MINNESOTA MEDICINE—365; 375 Jackson St., St. Paul 55101.

GENERAL PRACTITIONER urgently needed with two man partnership in Northern Minnesota County Seat Community has modern accredited hospital, stable industry, fine schools and excellent hunting and fishing. Contact Administrator, Roseau Area Hospital, Roseau, Minnesota. Telephone No. 218-463-2500.

MEDICAL DIRECTOR LIFE INSURANCE COMPANY—Position open for Medical Director of a major Life Insurance Company located in Saint Paul, Minnesota. This is a growth opportunity with officer status and offers liberal benefits plus profit sharing. Previous life insurance experience helpful, but not necessary. Salary open. If you are interested in exploring this position and the opportunity it offers, please write in complete confidence directly to the President. J. Willard Johnson, President, Western Life Insurance Company, Post Office Box 78, Saint Paul, Minnesota.

GENERAL PRACTITIONER wanted to join well established practitioner in city of 6,000 and serving a population area of 18-20,000. Approximately 70 miles west of Minneapolis-St. Paul. Well-kept clinic building two blocks from the hospital. Fully accredited 85 bed hospital with a Resident Pathologist, Radiological Service, LPN School, X-ray Technician School and complete Physiotherapy Department. Short-term association on salary basis or long-term association with eventual partnership; will accept, consider and appreciate either terms. Please send short resume of your education and previous experience. For further information about this opportunity write: MINNESOTA MEDICINE 431, 375 Jackson, St. Paul 55101.

WANTED: General practitioner to join two young general practitioners in well-established practice in suburban St. Paul. Excellent office space with lab, x-ray, and emergency room. Salary negotiable, with an association leading to early partnership opportunity. Write MINNESOTA MEDICINE 412, 375 Jackson St., St. Paul 55101.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with, early partnership. Write MINNESOTA MEDICINE—289; 375 Jackson, St. Paul, 55101.

CANOE TRIPS—Complete relaxation in the Quetico-Superior Wilderness. Cruise, fish and explore, or base camp on remote lakes. Paddle, motor or fly in. Bring your family—return home completely rested. Cost only $9.00 per diem, $7.00 under 12. Write: Bill Rom, Dept. MM, Canoe Country Outfitters, Ely, Minnesota.

WANTED: Young General Practitioner to join 5 man general practice group. Services of General Surgeon and Radiologist immediately available. College town serving population of 22,000, 30 miles from Twin Cities. Contact Roland M. Hammer, M.D., River Falls Medical Clinic, River Falls, Wisconsin. Phone 425-5322.

WANTED: General Practitioner for staff physician on General Medical Service. Regular hours. Generous fringe benefits, including outstanding retirement program. Nondiscrimination in employment. For further information contact Chief of Staff, Veterans Administration Hospital, Des Moines, Iowa 50309.

THREE PHYSICIANS WANTED: Emergency room at St. Paul, Minnesota, June 1, 1969. 450 beds, expansion 600 beds, 1970. Minimum guarantee $25,000 per year. Work week 28 hours. Contact Thomas W. Votel, M.D. 612-488-6777.

OPPORTUNITY FOR CAREER in occupational medicine with large corporation. Multiple locations. Salary plus fringes. Immediate openings in three locations. Give resume. Write: MINNESOTA MEDICINE—432, 375 Jackson, St. Paul 55101.

WANTED: General practitioner to join six man group, including two Ob-Gyn men, in well established practice in Minneapolis. Excellent opportunity for rapid ascent to full shareholder. Will consider locum tenens. Write: MINNESOTA MEDICINE-433, 375 Jackson, St. Paul 55101.

Case Reports

Black Leadership-Potential Psychological Crisis

Black equality is growing in America. Initial advances of racial desegregation[4] are evolving into actual integration of the black and white communities. These advances proceed through government legislation such as the Supreme Court Decision (1954) and the Civil Rights Bill (1964). Black people are encouraged to participate in integrative efforts by both interpersonal and intrapersonal forces, and participation in this drive for equality may result in black casualties. Although physical violence is publicized (assassinations of Medgar Evers and Reverend King, Jr.), psychological damage can also result both to the black individual and to his cause. Two examples follow.

Case 1

This middle-aged black woman was born out of wedlock in a Southern city. Her mother later married; but when the patient was six years old her parents were divorced. Until age twelve she was raised by her mother who was severely crippled from polio. On her mother's death she was cared for by relatives until her marriage at age seventeen. Her husband, a previous divorcee, and she have now been separated for three years due to his infidelity. Within this period she has raised her large family with the aid of A.D.C. Her activities include membership in an Urban Coalition Group, board responsibilities for several community centers, and lecturer on Afro-American history to schools and private groups. Her interest in integration is encouraged by both black and white citizens. She is a high-school graduate and is on high academic standing after college attendance last year. When seen for treatment she reported feeling suicidal and "not happy;" her anxieties were apparent in her pacing, her thinly-veiled hostility, and her ambivalence. Her past history disclosed that she joined many integration groups, accepted responsible positions, and then shortly became inactive. She was unable to admit or show weaknesses to those about her. Despite vocally endorsing the groups, she openly admitted a preference to return to the South and to reside there. Her working diagnosis was passive-aggressive personality.

Case 2

This young black lady was born in the South and abandoned on a doorway when she was six months old. She was raised by an aunt, as "my mother was beautiful, selfish, and went off and left me." At age eighteen she married but for the last six months has been separated, due to her husband's infidelity. She has supported her children by employment, but increasingly considers going on A.D.C. Her job is connected with a University integration planning program, and though only a high-school graduate, she works very capably at this sophisticated level. Other posts include community center instructor and campaign organizer for black political candidates; both white and black friends sponsor her in these activities. In the initial interview she was in an agitated state: she could not remember what had happened the preceding day and was unable to talk about herself. Visible anxiety was noted as she trembled and withdrew from noise. Tears appeared easily. She did not want to let her employers and friends down, though she volunteered that her committee pressures led to her hospitalization. When last seen she was unhappy, frustrated, and talked of moving back to the South. Her working diagnosis was dissociative reaction.

Discussion

The above two women demonstrate the environmental and social disadvantages that often appear in a black family. Both were unwanted children, raised in a matriarchal setting, with inadequate father figures. Their parents' hostile relationships culminated frequently with projection of anger upon the daughters. Their early life was spent in communities which emphasized white supremacy and passive-dependent roles for black citizens.[3] The two women participated in juvenile, disastrous marriages to men who did not provide security, and both were left as single parents in unfamiliar surroundings.

Search for recognition helped direct these ladies into integration groups—particularly when they were encouraged by other people who recognized the leadership potential. Thus these women became energetic, productive workers in integrative efforts. They were well-liked and respected. Increased control and command duties were assigned them in recognition of their fine work. But soon group responsibilities exceeded emotional capacities. Attempts to handle personal and racial anger failed. Compartmentalization of identity,[1] denial, avoidance and projection were tried. Failure of these ego defenses increased anxiety, led to cancellation of integrative group efforts, and supported regressive wishes to return to the infantile state. Their exploitation as potential negro leaders inadvertently resulted in a decline of their self-esteem and goals. Feelings of failure brought the desire to return to the social setting and position occupied by their parents.

Treatment Resource

Government recognition of community mental health includes not only integration legislation, but also legislation providing direct community psychiatric care. The Hill-Burton Act promotes government financing of community mental health centers. These funds, plus extraordinary efforts of the medical community, created the newly opened St. Barnabas-Swedish Mental Health Center. The government funds obligate the center to community involvement by making its primary responsibility a specific community or "catchment" area. Its obligations are not only the treatment, but the prevention of mental illness.

Conclusions

The two case histories support a need for direct concern with the integration movement at a mental health center. Both black and white in their pressure to achieve racial equality may put such strenuous demands upon a black citizen either through sociocultural environment or because of individual personality factors,[2] that he may be limited in his ability to respond to this challenge. The integration movement can poorly afford to lose black citizens with clearly demonstrated capabilities.

The nation, both black and white, should seek a gradual evolvement of community position for such people as the two women described above. The frenzy and pressure to achieve integration may deprive potential black leaders of personal happiness and the community of resourceful, responsible guidance.

The Mental Health Center is a potential help. First, it can provide inpatient or outpatient treatment for the frustrated community citizen pushed into areas of responsibility too rapidly. Second, the Center can provide an educative program within the community in hopes of preventing the above psychiatric casualties. It will be hoped that the St. Barnabas-Swedish Mental Health Center can rectify such tragedies as the above two case histories. A plan of community education, research, and clinical treatment by this health center can assist the legislated social concept of integration to become realized within our community in a manner non-destructive to participants.

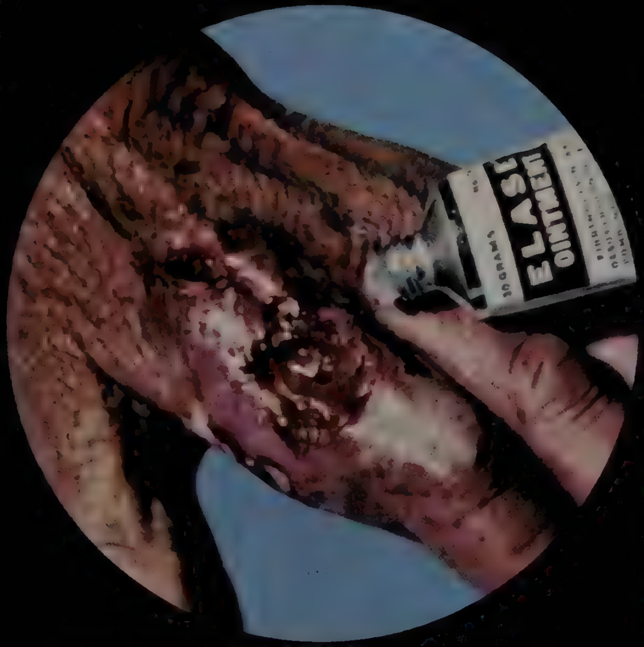
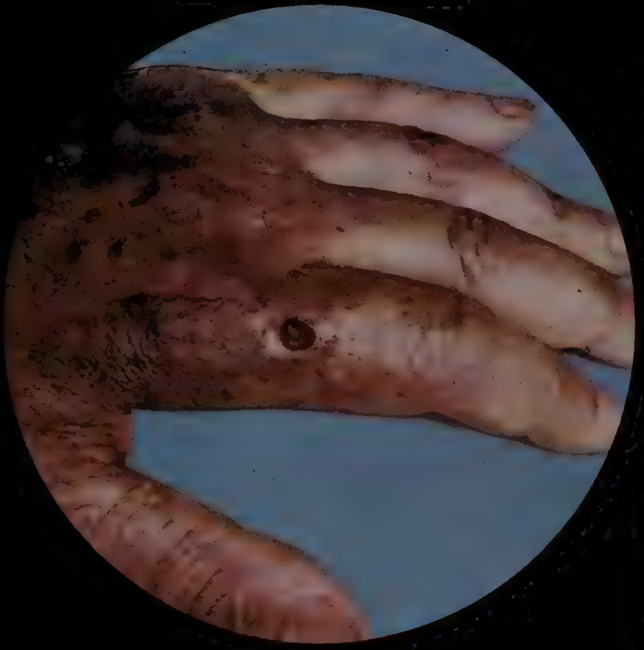
this ulcer did not heal...until its surface was cleared of dead tissue and debris



FIRST APPLICATION
ELASE Ointment is applied to a deep ulceration of a finger.

EIGHTEEN DAYS LATER
Healing has progressed rapidly without interruption or interference from any accumulated purulence or necrotic tissue. Greatly reduced size of lesion and minimal scar tissue indicate quality and vigor of healing which is almost complete.



to aid in debridement to facilitate healing in chronic cutaneous ulcers...

Elase® Ointment

(fibrinolysin and desoxyribonuclease, combined, [bovine] ointment)

PARKE-DAVIS

By helping to remove dead tissue and debris from the ulcer's surface, ELASE Ointment creates a better environment for the elimination of infection, for healthy granulation . . . *for healing.* Its lytic enzymes effectively break down DNA in dead leukocytes and other debris . . . the fibrin in blood clots, serum, and purulent exudates . . . and the denatured proteins in necrotic tissue. Protein elements of *living* tissue are relatively unaffected. ELASE Ointment is indicated in stasis ulcers and in other infected or inflamed ulcers caused by circulatory disturbances. In cases requiring skin grafting, it is used preoperatively for debridement. For ambulatory patients debridement with ELASE Ointment is a convenient therapy and a regimen likely to be followed. *Precautions:* Observe usual precautions against allergic reactions, particularly in persons with a history of sensitivity to materials of bovine origin or to mercury compounds. *Adverse Reactions:* Side effects attributable to the enzymes have not been a problem at the dose and for the indications recommended. *Discussion:* Successful use of enzymatic debridement depends on several factors: (1) dense, dry eschar, if present, should be removed surgically before enzymatic debridement is attempted; (2) the enzyme must be in constant contact with the substrate; (3) accumulated necrotic debris must be periodically removed; (4) the enzyme must be replenished at least once daily; and (5) secondary closure or skin grafting must be employed as soon as possible after optimal debridement has been attained. It is further essential that wound-dressing techniques be performed carefully under aseptic conditions and that appropriate systemically acting antibiotics be administered concomitantly if, in the opinion of the physician, they are indicated. *Available:* ELASE Ointment is supplied in 30-Gm. tubes containing 30 units (Loomis) of fibrinolysin and 20,000 units of desoxyribonuclease with 0.12 mg. thimerosal (mercury derivative); and in 10-Gm. tubes containing 10 units of fibrinolysin and 6,666 units of desoxyribonuclease with 0.04 mg. thimerosal. ELASE Ointment has a special base of liquid petrolatum and polyethylene; contains sodium chloride and sucrose used during manufacture; is stable at room temperature through the expiration date stated on the package.

the thousandth teaspoonful

Peptic ulcer patients find the thousandth dose of this antacid as effective and easy-to-take as the first!

Optimal neutralization—provided by the combination of aluminum and magnesium hydroxides.

Unfailing good taste—confirmed by 87.5% of 104 patients in one study, after a total of 20,459 documented days on Mylanta Liquid or tablets.[1]

Concomitant relief of G. I. gas distress—provided by the proven antiflatulent action of simethicone.[2]

Dosage: One or two tablets (well chewed or allowed to dissolve in the mouth); one or two teaspoonfuls to be taken between meals and at bedtime, or as directed by physician.

When it's more than a bad cold

your patient can feel better while he's getting better

Achrocidin®

Tetracycline HCl—Antihistamine—Analgesic Compound

Each tablet contains: ACHROMYCIN® Tetracycline HCl 125 mg.; Phenacetin 120 mg.;
Caffeine 30 mg.; Salicylamide 150 mg.; Chlorothen citrate 25 mg.

In tetracycline-sensitive bacterial infection complicating respiratory allergy, ACHROCIDIN brings the treatment together in a single prescription—prompt relief of headache and congestion together with effective control of the organisms frequently responsible for complications leading to prolonged disability in the susceptible patient.

For children and elderly patients you may prefer caffeine-free ACHROCIDIN Syrup. Each 5 cc contains: ACHROMYCIN (Tetracycline) equivalent to Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Salicylamide 150 mg.; Ascorbic Acid (C) 25 mg.; Pyrilamine Maleate 15 mg.

Contraindications: Hypersensitivity to any component.

Warning: In renal impairment, since liver toxicity is possible, lower doses are indicated; during prolonged therapy consider serum level determinations. Photodynamic reaction to sunlight may occur in hypersensitive persons. Photosensitive individuals should avoid exposure; discontinue treatment if skin discomfort occurs.

Precautions: Drowsiness, anorexia, slight gastric distress can occur. In excessive drowsiness, consider longer dosage intervals. Persons on full dosage should not operate vehicles. Nonsusceptible organisms may overgrow; treat superinfection appropriately. Treat beta-hemolytic streptococcal infections at least 10 days to help prevent rheumatic fever or acute glomerulonephritis. Tetracycline may form a stable calcium complex in bone-forming tissue and may cause dental staining during tooth development (last half of pregnancy, neonatal period, infancy, early childhood).

Adverse Reactions: *Gastrointestinal*—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. *Skin*—maculopapular and erythematous rashes; exfoliative dermatitis; photosensitivity; onycholysis, nail discoloration. *Kidney*—dose-related rise in BUN. *Hypersensitivity* reactions—urticaria, angioneurotic edema, anaphylaxis. *Intracranial*—bulging fontanels in young infants. *Teeth*—yellow-brown staining; enamel hypoplasia. *Blood*—anemia, thrombocytopenic purpura, neutropenia, eosinophilia. *Liver*—cholestasis at high dosage.

Upon adverse reaction, stop medication and treat appropriately.

The go-ahead-and-enjoy-your-vacation summer cold and allergy pill.

Novahistine LP lets you provide effective relief of summer cold and allergy symptoms, lets your patients go ahead and enjoy their vacations.

These continuous-release, decongestant tablets contain a vasoconstrictor-antihistamine formulation that goes to work promptly and lasts for hours. Even the nasal congestion resulting from repeated allergic episodes can usually be relieved by Novahistine LP.

And, convenient twice-a-day dosage lets most patients enjoy relief all day and all night. Use with caution in patients with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result.

PITMAN-MOORE Division of
The Dow Chemical Company,
Indianapolis, Indiana.

Novahistine®
LP decongestant

(Each tablet contains 25 mg. of phenylephrine hydrochloride and 4 mg. of chlorpheniramine maleate.)

DOW

Dermatology

Verruca Vulgaris

RECENT ELECTRON microscopic studies of human wart tissue have demonstrated the probable viral nature of this lesion. In the earliest stages of infectivity, viral particles are seen in the nucleus of the cells of the upper layers of the epidermis (stratum malpighii, granulosum, and corneum). Their size has been stated to be approximately 50 millimicrons. Interestingly, no viral particles have been observed in the lower layers of the stratum malpighii or basal cell layer. The viral particles are first arranged within the nucleus in regular or crystalline formations. Later the particles are dispersed within the nucleus and cytoplasm of the infected cell. These findings tend to correlate with the observations of light microscopy in which basophilic intranuclear inclusions are seen. Feulgan* reactivity would indicate that the central core of the virus contains DNA. The human wart virus has been classified as a member of the Papova virus group.

Immunology

Antibody (rabbit) has been observed in complex with human wart virus. Both pooled human gamma globulin and serum from patients with warts have been found to contain antibodies to wart in low titre. The weak response of the host can be attributed to the relatively inaccessible location of the virus (upper layers of the epidermis) with respect to the antibody-forming cells of the body.

Clinical

On the basis that there is an antibody response to human wart virus (albeit low) three clinical stages have been described. The first stage, which is most common in children, is characterized by the primary infection followed by the occurrence of additional lesions, presumably through auto-inoculation. In this stage there is little resistance (antibody titre). Removal of warts during this period is associated with a high rate of recurrence. In the next stage partial resistance develops and the spread ceases. However, resistance is not such that the wart disappears. Removal at this stage results in fewer recurrences. Finally, in the third stage, resistance increases to the level where the wart disappears.

It should be pointed out that the foregoing statements are not without controversy. Studies are continuing on this problem and perhaps the nature of infectivity and spread will be further clarified in the not too distant future.

Review

Placental Localization*

PLACENTA PREVIA is a serious complication of pregnancy that can occur with painless third trimester bleeding *and* malpresentation. According to Hibbard[1] an oblique or transverse lie, an eccentric fetal pole, or an excessively high vertex or breech, are not absolute clinical criteria for the diagnosis of placenta previa since only one third of patients with third trimester bleeding or malpresentation, or both, have placenta previa. The diagnosis may be directly made by means of vaginal examination in which the placenta is felt through the cervical os; but such examination should be done only in the operating room, where preparations have been made for immediate blood infusion and cesarean section in the event that hemorrhage occurs. This "double set-up" examination should not be done prior to 37 weeks' gestation, when the threat of prematurity exists, unless the quantity of blood being lost is excessive enough to dictate immediate termination of the pregnancy. Hence other means are necessary before 37 weeks to localize the placenta when loss of blood is not excessive.

Without placental localization, many of these preterm patients with third trimester bleeding not due to cervical or vaginal lesions might conceivably be hospitalized for the remainder of the pregnancy. Thompson and co-workers[2] estimated that three out of 100 hospital beds could be used for other purposes if the possibility of placenta previa could be excluded in these cases. Accurate localization of the various types of placenta previa has led to better management of the patient at delivery, with a resultant decrease in fetal and maternal mortality. Placental localization may also be indicated prior to amniocentesis and intrauterine fetal transfusion to avoid needle trauma to the placenta. Several of the localization techniques to be described are pictorially represented in the Figure.

Soft-Tissue Placentography

In 1934 Snow and Powell[3] first described visualization of the placental shadow with soft-tissue x-ray technique. Using anteroposterior and lateral views they found that the thickness of the uterine wall was relatively constant before labor; the placenta could be localized as an area of crescentic thickening of the uterine wall. With this technique they correctly localized the placenta in more than 90% of their cases. Some investigators noted difficulty with this technique when it was discovered that the amniotic fluid and the placenta have the same degree of radiologic densities and that errors could occur if accumulation of amniotic fluid was superimposed over soft tissues, giving the mistaken impression of the placental shadow. Tomography† has been suggested in these instances but has not been used because of the excessive radiation exposure to both the mother and the fetus.[4]

Contrast Cystography

Ude and associates[5] initiated the combined use of the soft-tissue technique and positive-contrast cystography. The relative thickness of the uterine wall between the fetal pole and the dome of the opacified bladder was measured, and if this thickness was greater than 2 cm, the presence of placenta previa was suspected. If the dome of the bladder was indented by the fetal pole, the possibility of placenta previa could always be excluded except for posterior placenta previa. In this case, a lateral pelvic roentgenogram was required. Negative-contrast study has been advocated, with the use of 200 to 300 ml of air injected into both the bladder and the rectum, to better visualize soft-tissue uterine densities and in cases of hypersensitivity to the iodinated dyes.[6]

Although the soft-tissue technique and cystography is an indirect means of localizing the placenta, visualization of placental calcification will directly localize its position. The calcification appears as finely or coarsely granular densities. Various studies reported visualization of placental calcification in vivo in from 31 to 50% of the cases at 32 to 36 weeks' gestation, with increasing chance of visualization as term approaches.[4]

Gravitational Placentography

In 1949, Reid[7] devised the method of gravitational placentography. Films were taken with the mother in the erect and the semi-erect position, allowing the fetus to gravitate into the lower uterine segment. Displacement of the fetal pole from certain regions of the maternal pelvis could thus be measured. The minimal distance between the presenting part and the sides of the pelvic inlet should be slightly greater than the thickness of the uterine wall. Reid estimated that the thickness of the lower uterine segment was not greater than 1.5 cm. An anteroposterior view is taken with the mother in the semi-erect position and a lateral view is taken in the erect position. Indirect localization of a placenta previa could be made if the following findings were present:[8] for *anterior placenta previa,* (1) anterior placental shadow (lateral view), (2) fetal head (pole) displaced more than 2 cm from pubis (lateral view), with or without lateral displacement (anteroposterior view); for *posterior placenta previa,* (1) posterior placental shadow, (2) fetal head (pole) displaced more than 2 cm from promontory, with or without lateral displacement; for *lateral placenta previa,* (1) lateral displacement of fetal head (pole), (2) presenting part may be within 2 cm of pubis or promontory.[8] A *posterior placental* shadow may not be visualized, owing to the increased density of the patient's body along the posterior wall of the uterus. If displacement of the fetal pole from the promontory is greater than 2 cm, a lateral view is taken with the mother semi-erect. If the pole falls into the posterior aspect of the pelvis, the possibility of posterior placenta previa is excluded.

Before this technique can be used, the physician must rule out the presence of a full bladder or rectum, pelvic masses, bony abnormalities of the pelvis, and a lax abdominal wall, which allows the fetal head to float. The accuracy of the technique is less with breech presentations, with transverse lies, and previous to 32 weeks' gestation. Reid excluded the possibility of placenta previa in more than 90% of his patients suspected of having it; however, in 44 patients with placenta previa diagnosed, he could confirm only 73% at delivery. Schreiber and Red[9] believe that this technique is accurate only when the placenta is normally situated, and that more direct methods of placental localization have now replaced soft-tissue placentography as the method of choice.

Amniography

Amniography, as developed by Menees and associates[10] primarily for the use of placental localization, was reported in 1930; but the contrast materials used at that time were frequently too toxic and caused premature labor. In addition, the possibility of needle injury to the fetus and its blood supply resulted in the relative disuse of this technique. With the perfection of the technique of amniocentesis and the development of newer, less toxic contrast materials, amniography became an acceptable procedure.

Technique

With the technique of amniocentesis, 30 to 50 ml of amniotic fluid are withdrawn and replaced with an equal amount of contrast material. Thirty minutes later an anteroposterior roentgenographic view of the pelvis is taken; if the placenta cannot be localized, a lateral view is taken. The placental edge can be seen as a filling defect where there is a disruption of the smooth outline of the amniotic sac. The placenta often shows small, rounded projections: the fetal surface vessels. Occasionally the cord can be seen if it is coated with dye. The possibility of placenta previa can be excluded if the fetal head is found in close contact with the smooth outline of the amniotic sac.[11]

Results

With this technique, the placenta can be localized before 32 weeks' gestation in patients with antepartum bleeding. Blumberg and coworkers[11] were able to differentiate low-lying, partial, and complete placenta previa. Although an indirect method, the technique has greater than 97% accuracy, with no false-positive results.[11,12] In a double-blind study of 30 patients in whom both the soft-tissue technique and amniography were used and in whom the location of the placenta was determined at delivery, three radiologists reviewing all the films made a total of 29 errors with the former method and only three errors with amniography.[13] Amniography will also reveal uterine deformities and tumors, soft-tissue anomalies of the fetus, hydatidiform moles, mono-amniotic or di-amniotic twins, fetal sex, and fetal viability.[14] Berner[13] and Blumberg and associates[11] did not incur any maternal or fetal complications with amniography.

Arteriography

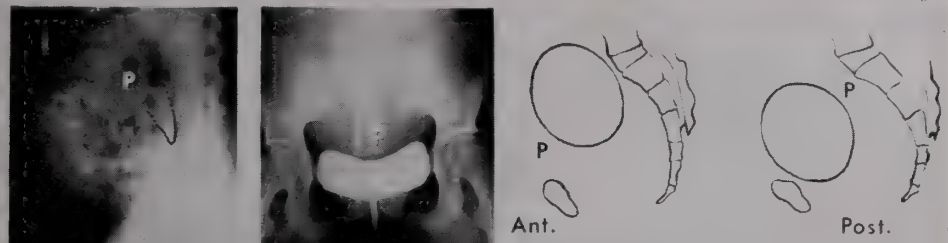
In 1929 Dos Santos[15] performed a translumbar aortogram for placental localization, and in 1952 Sutton[16] did the first retrograde femoral arteriogram for the same purpose.

Sedlinger Technique

After the femoral artery is punctured, a guide wire is passed through the needle into the external iliac artery, and the needle is withdrawn. A plastic catheter is then passed along the guide wire 20 to 24 cm to the distal portion of the aorta, above the bifurcation. The position of the catheter is then determined by fluoroscopy.[14] While the femoral arteries are compressed, 20 to 70 ml of contrast material are injected into the catheter, and roentgenograms of the pelvis are taken. Sutton[17] suggested that only one lateral view of the pelvis is needed, and during his procedure, the external os is marked with a vaginal speculum. Schreiber and Red[9] obtain a two-second film for the arterial phase and four-second and six-second films for the placental phase. Hedberg and Rådberg[18] take four anteroposterior views at varied intervals.

Results

Hedberg and Rådberg[18] defined the upper border of the lower uterine segment as a line between the promontory and 4 to 5 cm above



Soft-tissue Placentography

Figure—Techniques for placental localization.

the symphysis. The placental sinusoids are visualized as fluffy, white opacities; if none are visualized below the upper border of the lower uterine segment, the possibility of placenta previa can be excluded. A low-lying placenta exists when the sinusoids are present 3 to 4 cm below this border. As an aid in localizing the placenta, the internal os is located at the level where the uterine arteries, during the arterial phase, turn upward along the lateral margins of the uterus. If the opacities cover the area of the os, a total previa exists; if they are between this area and the one for a low-lying placenta, a partial or marginal placenta previa is present. Hedberg and Rådberg advocated the use of stereo films in the anteroposterior view to differentiate anterior and posterior placentas, or the use of a lateral film after a second injection.

In several studies[17-19] there was a 100% accuracy in localization, with no significant complications. The procedure can be done as early as eight weeks' gestation and can be used to diagnose other conditions such as ectopic or abdominal pregnancy, fibroids, and moles. Obesity, malpresentation, and hydramnios have no effect on the accuracy of this technique; however, the procedure is contraindicated in patients with hepatic or renal disease.

Intravenous Placentography

After the arm-to-tongue circulation time is determined, 75 ml of contrast material are rapidly injected into the antecubital vein. Two seconds plus the circulation time after the injection, an anteroposterior film of the pelvis is taken. Placental sinusoids appear as "cotton-ball" densities, and the placenta is easily viewed if it lies in the fundus or laterally, where the tangential view allows overlap of the sinusoids. Schreiber and Red[9] and Hendrick and Schreiber[20] found that intravenous placentography was more than 95% accurate; however, they were unable to differentiate a marginal placenta previa from a low-lying placenta. With a marginal previa, the sinusoids cover the fetal head, but with a complete placenta previa, there is less overlap of the sinusoids on the fetal head because of its displacement by the placenta.

This simple technique is accompanied by no complications and allows direct visualization of the placenta, though the roentgenograms are more difficult to interpret.

Isotopic Placentography

Radioisotopes were first used for placental localization in 1951 by Browne,[21] who used radioactive sodium (^{24}Na). Because of the short half-life and the rapid loss of this untagged substance from the blood into the tissues, ^{24}Na was regarded as a poor tracer. In 1957 Weinberg and co-workers[22] improved this technique, using radioactive iodinated serum albumin (RISA-131). With this material, the placenta can be localized in an area of increased radioactivity owing to the increased flow of blood to the placenta and the pooling that takes place there in relation to the surrounding structures.

Technique

At the Mayo Clinic the supine patient is given 5 μc of radioactive iodinated serum albumin-131 intravenously, and 10 minutes are allowed for dispersal of the material in the blood. A scintillation counter first records the gamma radiation over the precordium, which serves as a base line, and then over the uterus anteriorly. The abdomen is divided into 11 segments: three upper fundal, three miduterine body, three lower uterine, and one in each flank. The counter records the number of gamma emissions per minute from each segment, and the emissions are reported as counts per second for easier comparison. Other investigators record the counts as a percentage of the precordial count, and Hibbard[1] believes that the counts over the placenta ideally should be 1.5 to two times that of the surrounding uterus. Shanabrook[23] records each segment for one minute and then reverses the order and again counts the segments. The two counts for each segment are averaged and expressed as a percentage of the precordial count. The highest and lowest segments are averaged, and any segment that has a percentage count above this average represents the area of placenta.

Visual depiction of the placenta by scanning appears to be more anatomically correct than by scintillation, but this has not resulted in a greater clinical accuracy. Although more direct evidence of localization is present with the scan, more time is required for its recording and a larger dose of radioactive material is needed.[24]

Radioactive Substances

The ideal radioactive substance must remain in the blood for a reasonable length of time so that the recording can be done. Yet beyond this time, the rapid elimination of the radioactive material is desirable to keep the radiation exposure at a minimum. Human serum albumin is the preferred carrier substance because it is easily labeled, its metabolism is understood, and it does not cross the placenta in significant amounts. However, the use of albumin as a carrier modifies the rate of excretion of the isotopes from the body so that only seven to 10% are lost each day. The radioisotopes in current use for placental localization are radioactive iodinated serum albumin-131, 132 and 125, chromium-51, and technetium-99m.[19] Both radioactive iodinated serum albumin-131 and 125 dissociate into the free form, and the fetal thyroid must be protected with an iodine block by the administration of 10 drops of Lugol's solution several hours before the procedure and one day after the procedure.

Radioactive iodinated serum albumin-131 is easily produced and stored, and is commercially available. Because of its relatively long half-life of eight days, it can be given only in small doses of 5 μc. Also it emits beta rays, which are not recorded by the scintillation counter and which serve to increase the radiation hazard.

Radioactive iodinated serum albumin-125 must also be given in doses of 5 μc because of its long half-life of 60 days, but it is considered superior to radioactive iodinated serum albumin-131 because it is a pure gamma emitter.[1]

Radioactive iodinated serum albumin-132 has a half-life of only 2.3 hours and, as a result, can be given in higher doses, ranging from 50 to 100 μc. No block is required because of the short exposure time to radiation. However, it is not commercially available and has to be prepared prior to the test; in addition, it emits beta radiation.

Chromium-51 can be tagged to albumin or erythrocytes. The patient's own erythrocytes are used, and the tagging preparation takes about one hour. If an emergency situation arises, banked, tagged blood that is group O and Rh negative can be used; such blood has the advantage of not crossing the placenta, and no preparation or block is necessary. It has a half-life of 27.8 days and can be given in a dose of 20 μc.[1]

Technetium-99m promises to become the most effective tracer substance. It is a pure gamma emitter, has a half-life of six hours, and can be administered in doses of 200 to 500 μc without the use of a preliminary block. Because such a high dose of radioactivity can be given, the scanning technique can be used.[25] However, the substance must be prepared prior to the test, and most hospitals do not have the proper isotope facilities for this.[1]

From a genetic standpoint, all radiation is potentially dangerous. It is cumulative and there is no lower limit of exposure that is safe. According to Hibbard,[1] the various x-ray methods of placental localization produce a considerable amount of radiation exposure to both the fetal and maternal gonads. If two roentgenograms of the pelvis are taken, the fetal and maternal gonads each receive an exposure of 1,000 mrems. One of the main advantages of isotope placental localization is the considerably smaller radiation exposure. With the recommended dosage of the various isotopes, the calculated radiation exposure to the fetal and maternal gonads ranges from 0.5 to 15 mrems.

The results of isotope placentography have been excellent; the accuracy ranges from 93 to 100%.[1,2,25-27] In most studies there were no false-positive results. Inaccuracies result from difficulty in localizing posterior placentas, whether normally or abnormally situated. Weinberg and associates[28] reported that high counts in the flanks are suggestive of a posterior placenta. Some investigators recommend either a vaginal[29] or a perineal[23] recording to localize a posterior placenta previa. Others advocate a lateral scan.[30] False-negative results occur because of the difficulty in distinguishing a low-lying placenta from a marginal placenta previa.

Thermography

The increased vascularity and metabolic activity of the placenta produce more heat than do the surrounding structures, and this heat is conducted directly to the skin overlying the placenta. The increase in infrared radiation, which is a function of the temperature, can be recorded in less than five minutes in the form of a two-dimensional thermoplacentogram: a technique entailing the use of specialized, expensive equipment.

Birnbaum and Kliot[31] reported an error of only 3.7% in localizing the placenta in their study of 53 patients. Others are not as enthusiastic, citing the technical difficulties and expense of the procedure and the difficulty in localizing posterior placentas.[9,14,32,33] Some believe, however, that this method is only in its infancy, that more work must be done to refine the technique, and that the method has promise as a useful procedure for placental localization.

Ultrasonic Placentography

Localization of the placenta using ultrasound is based on the Doppler principle: the ultrasound waves directed into tissue are reflected off surfaces and are recorded by a transducer. When these waves are reflected from a moving target, the frequency is changed; it is amplified, filtered, and converted either into an audible signal or into a visible one as recorded by an oscilloscope.[34]

Motion of the fetal heart and blood flow in the cord, placenta, and the maternal and fetal vessels can be detected. Each has its own characteristic sound, including the placenta. Location of the "placental sound" will establish its position.[35] With the patient supine, the abdomen is divided into nine segments, and each segment is searched with the transducer. When the placental sound is found, it is possible to determine whether the placenta is anterior or posterior. If anterior, the echo waves are confined to a small area; if posterior, the echo waves are scattered and recorded over a wider area because of the distance between it and the transducer. In addition, a posterior placenta may be suspected if there is loss of parts of the placental sound over this wide area because of the interposition of the fetal body or small parts. Maternal blood flow can be distinguished from fetal blood flow by the difference in heart rate; maternal arterial sounds are synchronous with the pulse; and maternal venous sounds, although they vary, can be identified when they are obliterated, with an increase in the intra-abdominal pressure.[34]

This technique actually does not localize the placenta but rather localizes the point where the cord inserts into the placenta. Thus the margins of the placenta cannot be localized. The distance between the placental edge and the cord insertion depends on the size of the placenta, which is essentially a function of its age. Brown[34] calculated that the placental diameter, starting at 15 to 19 weeks' gestation, is 10 cm and increases 2 cm every four to six weeks, to a maximum diameter of 18 cm at 34 weeks. Assuming that most cords are eccentrically inserted into the placenta, one can estimate the distance of the placental edge from the cord by taking 60% of the diameter at that gestational time and using this figure as the overall radius of the placenta to obtain the theoretic placental margin.[34]

A new technique in ultrasound recording has been described in which the entire anatomic area is scanned and the sounds are recorded by the oscilloscope and converted into one composite picture. The placenta is visualized in cross section as a thin but compact area of multiple echoes or small white dots appearing beneath the outline of the uterine wall. Taking pictures at 2-cm intervals in both the horizontal and the sagittal plane makes it possible for the location and boundaries of the placenta to be plotted graphically.[36] These investigators hypothesized that, with refinement in technique and equipment, placental abnormalities such as marginal sinus separation and circumvallate placenta can be diagnosed.

Brown,[34] using the Doppler ultrasonic technique, obtained an accuracy of 91%; Gottesfeld and associates,[36] using the composite oscilloscope method, found a correct diagnosis in 97% of their cases. This ultrasonic technique is comfortable for the patient, has no side effects or radiation hazards, can locate the placenta at 20 weeks' gestation, and can be used serially throughout the patient's pregnancy.

Conclusion

The proponents of each of the various techniques of placental localization stress the safety, accuracy, and simplicity of their methods. Because the accuracy of most of these techniques is generally better than 90%, it is difficult to say which one is the best. All have certain advantages and disadvantages which must be considered when a method for placental localization is selected. Factors to consider are: direct-versus-indirect localization, cost of equipment and availability of facilities, ease to patient and preparation required, technical skill, radiation hazard, complicating factors (obesity, hydramnios, breech), gestational time, contrast-media hypersensitivity, and duration required for technique in emergency situations.

Science

Science must have a heart as well as a head. Science must be understood for what it is—an instrument, and only that, which the mind of man had conceived for quarrying into the unknown. But it is not a deity. No civilization has ever endured in which science had no objectives but its own deification. No civilization has ever endured in which scientific progress was without a moral equivalent.*

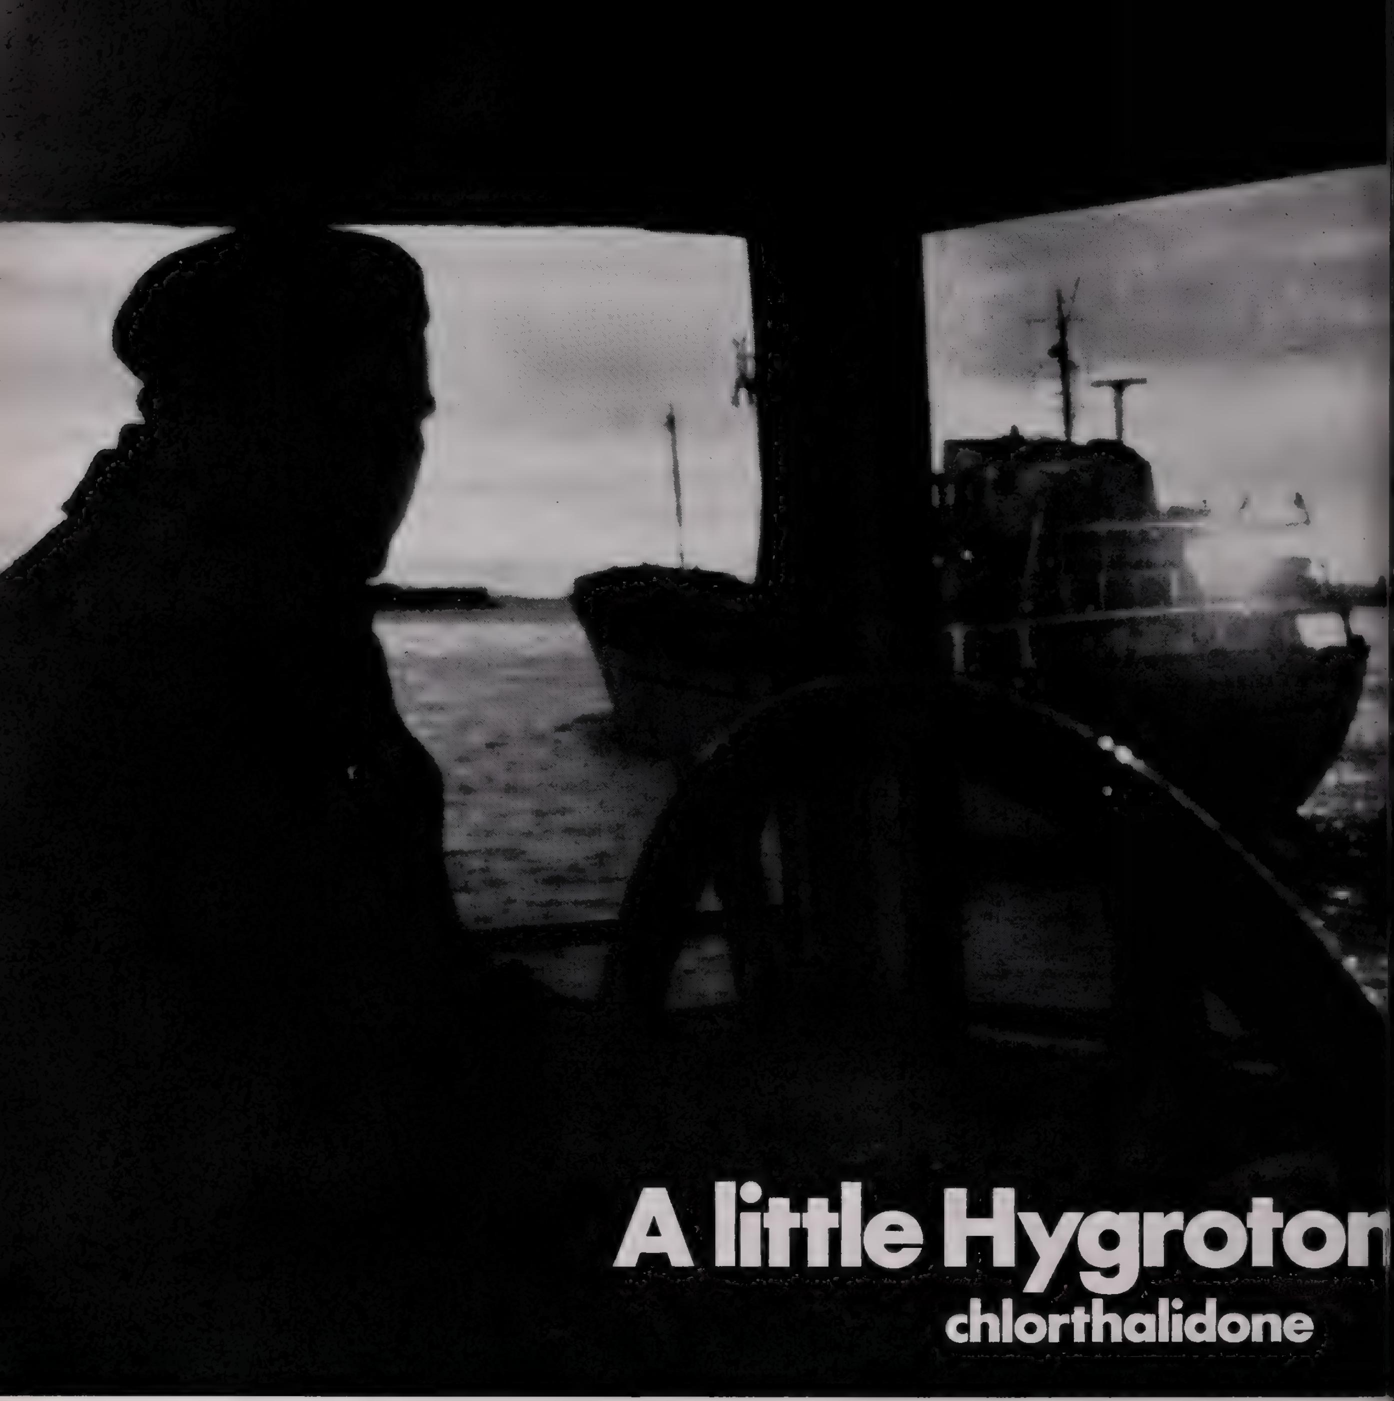
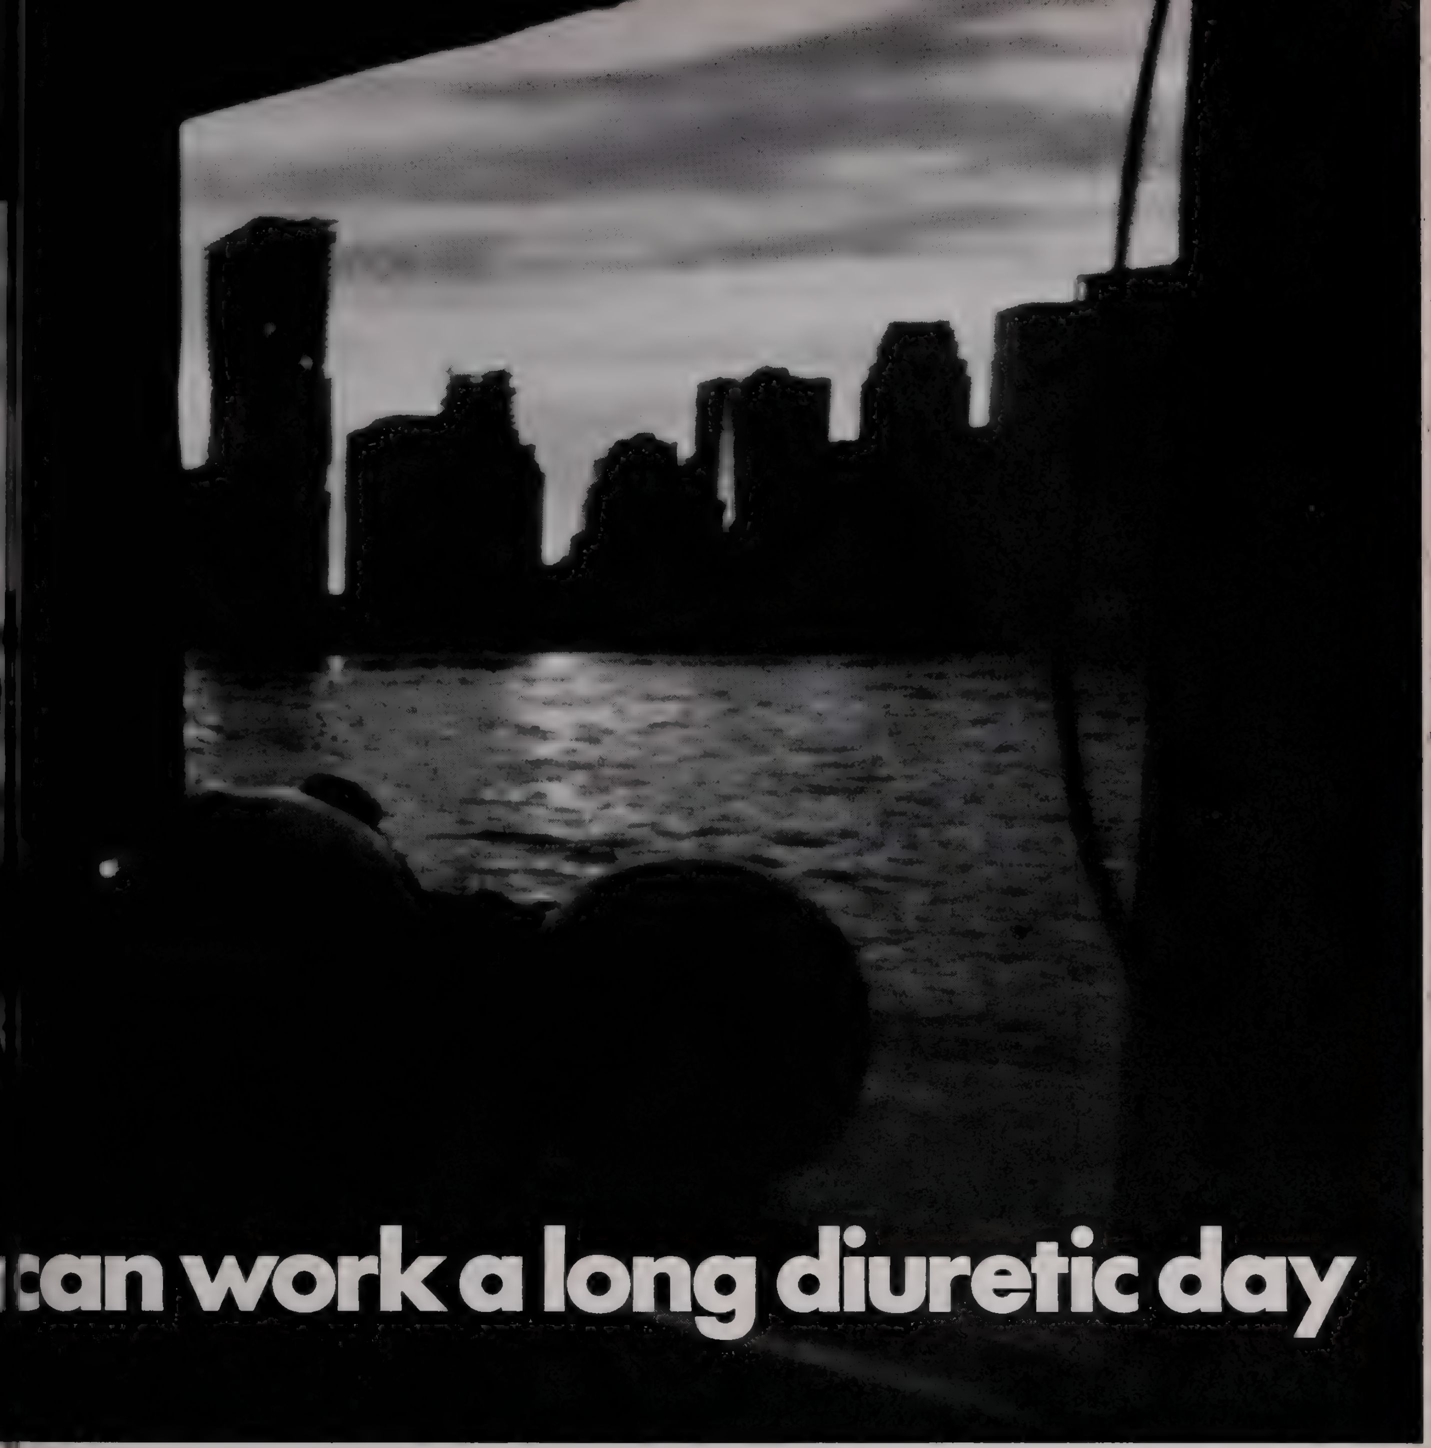
Gentleman: a man who is always as nice as he sometimes is.



A little Hygroton
chlorthalidone

HY-6674



ll the way from one daily tablet to the next
help control edema and hypertension

s prolonged action usually provides smooth, sustained diuretic fectiveness; real one-a-day dosage, right from the start; convenience nd economy.

ygroton, chlorthalidone, can cause side effects. And it's contra-dicated in hypersensitivity to the drug and severe renal and epatic diseases.

heck the prescribing information. It's summarized on the next page.

Geigy

A little Hygroton® can work a long diuretic day

chlorthalidone

Indications: Hypertension and many types of edema involving retention of salt and water.
Contraindications: Hypersensitivity and most cases of severe renal or hepatic diseases.
Warning: With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has been required frequently and deaths have occurred. Discontinue enteric-coated potassium supplements immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur.
Use with caution in pregnant women and nursing mothers since the drug may cross the placental barrier and appear in cord blood and since thiazides may appear in breast milk. The drug may result in fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. When used in women of childbearing age, balance benefits of drug against possible hazards to fetus.
Precautions: Antihypertensive therapy with this drug should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents, other potent antihypertensive drugs or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. Because of the possibility of progression of renal damage, periodic determination of the BUN is indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated.
Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, the drug should be discontinued and potassium supplements given, provided the patient does not have marked oliguria.
Take special care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.
Adverse Reactions: Nausea, gastric irritation, vomiting, anorexia, constipation and cramping, dizziness, weakness, restlessness, hyperglycemia, glycosuria, hyperuricemia, headache, muscle cramps, orthostatic hypotension, which may be potentiated when chlorthalidone is combined with barbiturates, narcotics or alcohol, aplastic anemia, leukopenia, thrombocytopenia, agranulocytosis, impotence, dysuria, transient myopia, skin rashes, urticaria, purpura, necrotizing angiitis, acute gout, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Other reactions reported with this class of compounds include: jaundice, xanthopsia, paresthesia, and photosensitization.
Average Dosage: 50 or 100 mg. with breakfast daily or 100 mg. every other day.
Availability: White, single-scored tablets of 100 mg. and aqua tablets of 50 mg., in bottles of 100 and 1000.

Grand Rounds

Needle Biopsy of the Parietal Pleura*

ANDREW E. EDIN, M.D.
Minneapolis, Minnesota

In 1954 Sutliff et al. called attention to the diagnostic efficacy of open pleural biopsy in the diagnosis of pleural diseases associated with pleural effusions.[1] This was soon followed by adaptation of the Vim-Silverman needle to biopsy of the parietal pleura by DeFrancis et al.;[2] and since 1955 it has been repeatedly demonstrated that needle biopsy of the parietal pleura is an important means of diagnosis of tuberculous and malignant pleural effusions.[2,20]

It soon became evident that the Vim-Silverman needle had at least one serious disadvantaged that militated against its routine use for pleural biopsies; an adequate specimen is frequently not obtained.[17,19] In addition, it is potentially dangerous, especially when there is little or no pleural effusion, because of the likelihood of removing a core of lung tissue at the time of biopsy. It is also reported that there is considerable distortion in the histologic appearance of the specimen.[20] These difficulties stimulated the design and manufacture of six new needle biopsy instruments.[23,24,15,25,26,27] In 1958 Abrams[24] and Cope[15] each introduced blunt-end needles especially designed to biopsy pleura. Since their introduction many authors have stated their preference for blunt-end needles.[13,19,20,17,10] The Cope needle appears to have gained wider acceptance in the United States, whereas the Abrams (Harefield) needle has been more widely used in Britain and Europe.

Methods

The purpose of this paper is to review our experience with blunt-end needle biopsies of the parietal pleura and to compare it with the experience of other physicians and institutions.

---

*Presented as a Medical Grand Rounds at Hennepin County General Hospital, December 19, 1967.

The records of the Hennepin County General Hospital Department of Pathology for the period 1 January, 1965, through 1 December, 1967, were reviewed. All specimens entered as "pleural biopsy" were noted and the name and number of the patient recorded. Pathology reports of all pleural needle biopsy specimens were reviewed and the slides reinterpreted by a staff pathologist.

The charts of all patients thus selected were reviewed, and the final diagnosis establishing the etiology of the pleural effusion was determined, utilizing histologic or bacteriologic evidence whenever possible. Autopsy results were also evaluated whenever available. In some patients the final diagnosis was based on clinical grounds.

The techniques employed in obtaining pleural biopsies were those described by Cope[15,19] and Abrams.[24] The post-biopsy x-ray reports and physicians' progress notes were reviewed on all patients to discover any complications of the biopsy.

Case Reports

Case 1

An 84-year-old white male was admitted to the Medical Service with complaints of weight loss and weakness of three weeks' duration. He was a vague historian but had apparently been well until the onset of weakness, which was especially marked in his legs. He had not been out of bed for the two weeks prior to admission. He was a non-smoker. A chest x-ray on admission showed a right pleural effusion but no evidence of cardiomegaly or congestive heart failure.

Physical examination revealed a well developed, elderly white male. Breath sounds were decreased over the right lower hemithorax posteriorly, and there was dullness to percussion over the same area. The temperature was 98.6°; blood pressure 170/80; pulse 80. Hemoglobin on admission was 12.3, white blood count 5,600 with a normal differential. Thoracentesis was performed one day after admission. Four hundred cubic centimeters of serous fluid were withdrawn: 3.2 grams of protein, sp. gr. 1.027, white blood count 400 with 86 mononuclears, 14 PMN, red blood count 11,000. Culture and smear were negative for tubercle bacilli and also for malignant cells. Sputum culture grew out Pseudomonas. Circulation time, arm to tongue, was 24 seconds. Fungus skin tests were negative. Intermediate strength purified protein derivative skin tests on two occasions were read as negative. A second strength purified protein derivative was likewise reported as negative. Circulation time repeated one week later was 18 seconds. Prothrombin time was 14.9 seconds and partial thromboplastin time 41 seconds. One week after admission, a pleural biopsy was performed with the Cope needle, along with the withdrawal of 500 cc. of serous fluid. The pleural biopsy reported: "Several distinct granulomas are seen which contain epithelioid cells and some giant cells of the Langhans type, 'consistent with tuberculosis'."

The patient was transferred to the Adult Isolation Service; a repeat intermediate strength purified protein derivative was positive with 9 mm. induration at 48 hours. Multiple sputum specimens were negative for acid-fast bacillus on smear and culture, as was the pleural fluid. The patient was begun on Isoniazid 300 mg./day and pyridoxine 25 mg./day and was transferred to Glen Lake Sanitarium.

Case 2

A 57-year-old white male was admitted to the Adult Isolation Service with a chief complaint of chest pain and dyspnea of three weeks' duration. He was noted to have a pleural effusion on the right when an admission chest x-ray was obtained in Emergency Receiving. His past medical history included hospitalization at Glen Lake Sanitarium some 15 years previously for pulmonary tuberculosis, and a more recent diagnosis of chronic obstructive lung disease and bronchiectasis. He was a heavy smoker.

Physical examination on admission revealed a dyspneic white male with a respiratory rate of 40, blood pressure 146/86, pulse 90 and temperature 102° F. There was very extensive clubbing of the fingers and toes. Decreased breath sounds and dullness to percussion were noted at the right base posteriorly, extending up to T-7; and a Grocco's triangle was present on the left. The liver was down three centimeters below the right costal margin. Admission x-ray revealed a right middle lobe, right lower lobe infiltrate and a large right-sided pleural effusion. His admission diagnosis was pneumonia with effusion. Sputum culture grew pneumococci. Hemoglobin was 15.8; white blood count 13,800 with a shift to the left.

On the day of admission 1,000 cc. of serosanguineous pleural fluid was removed from the right chest: sp. gr. 1.015, protein 2.9 grams, cell count 2,300 with 87 PMN and 13 monos. RBC was 40,000/cu. mm. Prothrombin time was normal. Multiple thoracenteses were performed with an average of 2,000 cc. of serosanguineous pleural fluid being withdrawn every two or three days. One week after admission a pleural biopsy was performed with the Abrams needle and reported as "benign, with fibrosis." Pleural fluid was negative for malignancy on two occasions and suspicious for malignancy on three occasions. Two weeks after admission a bronchoscopy was performed with multiple negative bronchial biopsies and negative bronchial washings. A second strength purified protein derivative was positive; multiple sputum and pleural fluid cultures were negative for acid-fast bacillus. Repeat pleural biopsy was done three weeks after admission and reported as showing "metastatic invasion of the pleura, primarily thought to be a bronchiogenic carcinoma, possibly a small cell carcinoma." Chest tubes were placed and HN_2 was instilled, which controlled the effusion and gave the patient considerable relief of his dyspnea. He was transferred to "Our Lady of Good Counsel" one month after his admission.

Results

From 1 January, 1965, to 1 December, 1967, 42 patients, nine women and 33 men, ranging in age from 17 to 90, with a median age of 65, underwent a total of 46 pleural biopsies. Of these, 41 were performed with the Cope needle and the remainder with the Abrams (Harefield) needle. Forty-one of the 42 patients had a pleural effusion at the time of the needle biopsy.

Complications

Out of 46 biopsies there was no mortality and no clinical morbidity. There were four asymptomatic pneumothoraces, none of which required chest tubes for resolution. These were small pneumothoraces, probably related to introduction via leakage of air through the biopsy needle. There were no tension pneumothoraces. Lung tissue was reported in one biopsy specimen, as well as pleura; and normal liver tissue was reported in two biopsies.

Malignant Effusions

As can be seen in Table 1, 15 patients who were subsequently found to have malignancy associated with effusion, underwent 17 needle biopsies. In seven of the 15 patients, a diagnosis was established. Thus in almost 50 per cent of the known malignant effusions the needle biopsy established the diagnosis. As can be seen in Table 2, two of the seven positive biopsies were obtained on the second attempt. Of the remaining eight patients who were subsequently demon-

strated to have malignancies, none were re-biopsied, despite the fact that three of the eight were reported as having yielded inadequate specimens. One of these three patients subsequently had a thoracotomy which demonstrated metastases to the pleura. The remaining five had nonspecific pleurisy or fibrosis on the biopsy. Of the seven that did not have a diagnosis established by either needle or surgical biopsy, two were proven at autopsy to have had malignant pleural involvement and one was proven at autopsy not to have had pleural involvement. In conclusion, about 50 per cent of malignant effusions had a positive needle biopsy of the pleura, and approximately 30 per cent of the diagnoses were established on the second biopsy attempt.

Tuberculous Pleural Effusions

As can be seen in Table 3, there were only four patients in whom a diagnosis of tuberculous pleural effusion was established in this series of 42 patients, and of these four patients three were diagnosed solely on the basis of the biopsy. (Plus a positive skin test and an otherwise idiopathic pleural effusion.) Only one patient was found with an effusion, positive sputum cultures for tuberculosis, and a negative pleural biopsy. As before, on the patients with malignancy the biopsy was not repeated when the diagnosis of "nonspecific pleurisy or fibrosis" was recorded by the pathologist. Table 4 shows the results of pleural biopsy performed on 23 patients demonstrated to have neither cancer nor tuberculosis.

Non-diagnostic Biopsies

Inadequate biopsies comprised nine of the 46 specimens, or approximately 20 per cent. Eight of these did not have pleura submitted, just intercostal muscle and fat; the other inadequate specimen was hepatic tissue. Of the nine patients with inadequate biopsies, only one was re-biopsied and a diagnosis of carcinoma made. Of the remaining eight, three were subsequently proved to have carcinoma.

There were 23 biopsies on 20 patients in which a pathologic diagnosis of non-

specific fibrosis or inflammation or pleuritis was made. Of these 20 patients only two were re-biopsied, and, as has been previously stated, one of these re-biopsies made the diagnosis of carcinoma. Out of the 20 patients with non-specific changes, six had malignancies and one had tuberculosis.

Summary of Studies

Forty-two patients underwent 46 needle biopsies of the pleura. Ten had positive diagnoses of carcinoma or tuberculosis established by needle biopsy, out of a total number of 19 patients, who subsequently were demonstrated to have either carcinoma or tuberculosis. This is a diagnostic "accuracy" of just greater than 50 per cent. In view of the high yield of re-biopsy (two of the three patients subjected to re-biopsy had a definite diagnosis of malignancy established), it is interesting to speculate what the yield might have been had all patients with a non-diagnostic initial biopsy been subjected to re-biopsy. None of the patients had any significant complications as a result of the biopsy. In our series, only one biopsy specimen was sent for tissue culture out of 46 biopsies performed.

Comment

Needle biopsy of the pleura has proved to be an effective and useful diagnostic procedure, as reported by many investigators.[2,20] Table 6 summarizes the diagnostic accuracy as reported by some of the many investigators who have published their experience. Virtually all of the reported series have stressed the fact that a histologic diagnosis of non-specific pleuritis, chronic inflammation, or fibrosis on the initial biopsy is, in fact, not a diagnosis at all. Virtually all authors have stressed the need for re-biopsy when a non-specific histologic picture has been obtained on the initial biopsy. Rao et al.[7] found nine of 32 cases with non-specific inflammation on initial needle biopsy to have either carcinoma or tuberculosis. Table 7 demonstrates the frequency with which the diagnosis was established by repeated biopsy in one series of 151 patients.[17]

Safety

The complications reported in the literature include pneumothorax, hemothorax, hepatic biopsy, lung biopsy, and intercostal neurectomy.[17,20,22] It has been the practice at Hennepin County General Hospital to perform pleural biopsy only in the presence of a demonstrated pleural effusion. However, Cope[15] specifically designed his biopsy needle to be used in the absence of pleural effusions. Three authors have reported their experience with this needle when used in the absence of effusion at the time of biopsy.[15,17,20] Niden et al. reported on 19 patients. Six had lung tissue in the biopsy without developing pneumothorax; three had small asymptomatic pneumothoraces; one patient with multiple subcutaneous hemorrhages but no demonstrable bleeding dyscrasia had a hemothorax. A positive diagnosis was established in seven of the ten patients with proven malignancy or tuberculosis.[20]

Levine and Cugell[17] reported 44 patients without effusion. In 90 per cent an adequate biopsy was obtained. One third had lung tissue in the biopsy; none had any complication as a result of this inadvertent lung biopsy. One patient who was already moribund from widespread carcinomatosis died five days after the biopsy. There seems to be no more morbidity or mortality associated with pleural biopsy in the absence of effusion than in the presence of effusion.

Case Selection

Several studies have been reported in which the diagnostic yield was reported as a percentage, based on the total number of patients or biopsies, and the number of positive diagnoses established by biopsy. This is misleading when one

*From Levine & Cugell[17].

attempts to ascertain the usefulness of any procedure, because prior case selection has such a great influence on diagnostic yield. Levine and Cugell[17] have shown, in a well-done study, the effect of careful prior case selection on the diagnostic yield. In their initial series, all patients with pleural effusions were biopsied, including those with obvious cardiac, renal and hepatic disease. They reported only 12 per cent positive biopsies. Their last 50 patients, selected with the criteria they developed, had a 68 per cent incidence of positive biopsies. Then for control purposes, they did 48 biopsies on 16 patients with pleural effusions, who did not meet their criteria, and none of these patients had positive biopsies, thus indicating that their criteria were probably not overly restrictive.

Their criteria:

"1. Any pleural effusion *not* occurring as a part of the clinical picture of congestive heart failure, cirrhosis, nephrosis, collagen disease, pneumonia, or trauma to the involved hemithorax;

2. Pleural fluid characteristic of an exudate (protein concentration above 2.5 gm.%) when a transudate was expected, e.g., congestive heart failure;

3. An area of unresolved pneumonitis impinging upon the chest wall—impingement considered likely if there was: (a) a history of localized pain, (b) physical findings of consolidation, pneumonitis, or localized swelling persisting for several weeks, and (c) roentgenologic evidence of contiguity with the chest wall."

Additional experience has shown[18] that patients with pulmonary embolus/infarct and empyema will have only non-specific pleural changes on repeated biopsies; and, in these cases, if a strong clinical case can be made, there is little reason to expect helpful information from pleural biopsy.

Bacteriology

As previously indicated, it has not been the practice at Hennepin County General Hospital to do bacteriologic cultures of pleural biopsy tissue specimens; however, Weichelhausen et al.[21] have reported positive tuberculosis cultures in six of 14 patients with tuberculous pleural effusions. In three of the six patients, the growth of M. tuberculosis was the only definitive evidence that these patients had tuberculosis, the pleural fluid cultures and pleural biopsy histology both being negative. Therefore Weichelhausen and colleagues recommend the immediate placement of the biopsy specimen in *Tween*® albumin medium, and the use of Dubos liquid medium for culture, because of its ability to support the growth of both M. tuberculosis and various fungal agents.

Contraindications

The only absolute contraindication to pleural biopsy would appear to be a bleeding tendency, although Cope[19] reported no untoward reactions in patients with prothrombin time as low as 40 per cent of normal. The absence of pleural effusion can be considered a relative contraindication at most; and the authors who have performed biopsies in the absence of effusion have reported minimal, if any, increase in morbidity and apparently do not consider the lack of effusion to be a contraindication. It would seem judicious to be cautious in the employment of this technique in the absence of effusion, and to have the biopsy performed by the most experienced physician available; but to judge from the experience of others, little difficulty is likely to be encountered.

Conclusions

Blunt-end, hook-needle biopsy of the parietal pleura is a safe, effective means of diagnosing disease involving the pleura. The diagnostic yield, with proper prior case selection, should approach 75 per cent in the diagnosis of tuberculous and malignant pleural effusions. Non-specific fibrosis or inflammation reported as a histologic diagnosis is not a clinical diagnosis; and, if the indications for biopsy were present for the initial attempt, the biopsy should be repeated to obtain a more definitive diagnosis, even in the absence of a recurrence of the pleural effusion. Our experience indicates a higher incidence of inadequate biopsies than several other series using the Cope needle. This probably reflects the large number of biopsies done by relatively inexperienced personnel, and perhaps inadequate prior familiarization with the proper technique. Bacteriologic cultures of pleural tissue represent an area of diagnostic effort that is not being utilized at present.

Visceral Larval Migrans Syndrome

This childhood syndrome consists of chronic eosinophilia and hepatomegaly associated in some cases with pulmonary involvement. Although Stewart (1933) first described two cases now recognized as the syndrome, Zuelzer and Apt (1949) described eight cases as comprising a distinct clinical entity with autopsy findings in one case. Children from one to four years of age are usually affected. At least 19 cases have been reported.

Clinical manifestations consist of chronic persistent hyperleukocytosis, moderate to severe eosinophilia, hyperglobulinemia, hepatic enlargement, and in some cases splenomegaly and pulmonary infiltration with symptoms of mild to moderate pneumonitis, often recurrent. Occasionally there is serious respiratory, central nervous system, or eye involvement.

The etiologic agent in some cases has been proved to be liver invasion by nematode larvae. Biopsy has revealed eosinophilic infiltration and granulomatous lesions that contain larvae, shown by some investigators to be due to the ingestion of embryonated ova of dog or cat roundworms (*Toxocara canis* and *T. mystax*), as well as *Ascaris lumbricoides.* The course is self-limited but of long duration. A number of cases were asympatomatic, but the clinical findings in all cases persisted from one month to three years; nevertheless each child showed normal growth and development. Antihelminthic therapy is indicated, but it does not always alter the course.

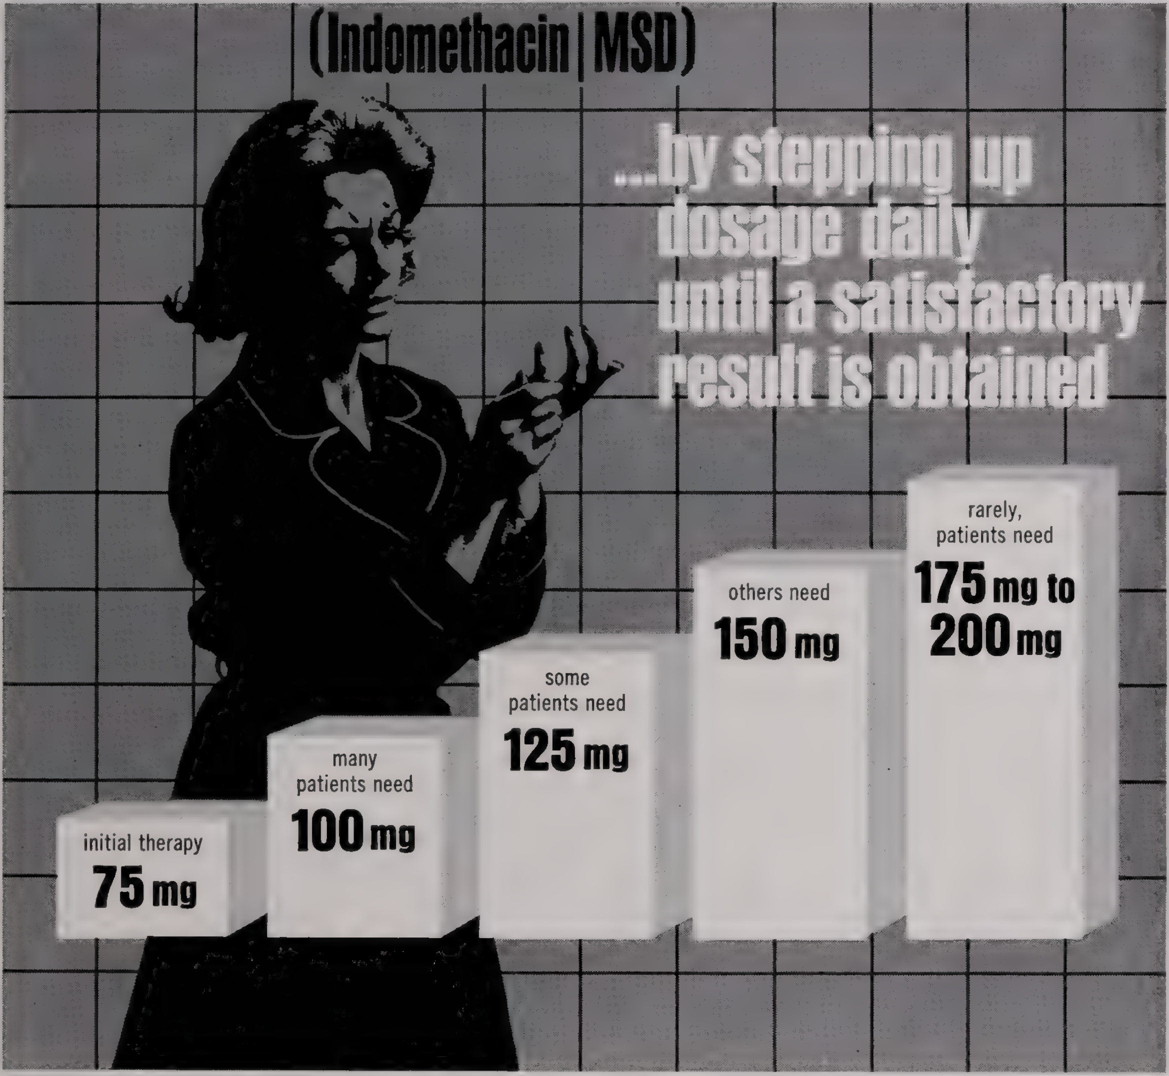
Tact consists in knowing how far to go in going too far.—Cocteau

In selected cases of rheumatoid arthritis
with acute symptoms

Response to INDOCIN® is often improved...



Many patients with acute rheumatoid arthritis or acute episodes of chronic rheumatoid arthritis can be controlled by increasing the dosage 25 mg *per day* (to the allowable maximum) until the episode subsides; the dosage should then be reduced gradually to maintenance levels. Few require the maximum (175–200 mg).

In the event the patient develops adverse effects, dosage should be reduced to tolerated levels for 2 or 3 days and then gradually increased by 25 mg every few days as tolerated. G.I. effects may be minimized by giving INDOCIN with food, antacids, or immediately after meals.

Now in two strengths
25 mg and 50 mg

MSD 25
MSD 50

Actual Size

INDOCIN®
(Indomethacin|MSD)

IMPORTANT NOTE: INDOCIN (Indomethacin, MSD) cannot be considered a simple analgesic and should not be used in conditions other than those recommended under *Indications*. The drug should not be prescribed for children because safe conditions for use have not been established.

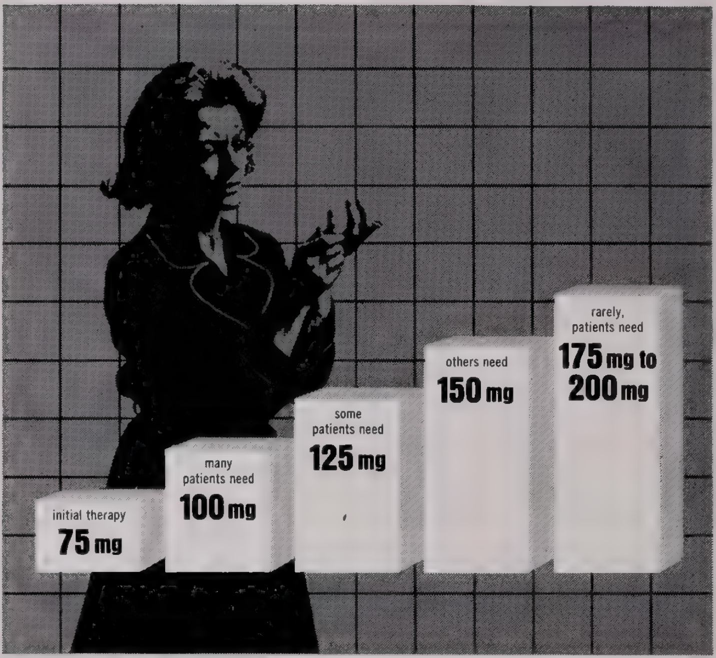
CONTRAINDICATED:

- in aspirin-sensitive asthmatics
- during pregnancy or lactation
- in children
- INDOCIN may mask the signs and symptoms of peptic ulcer and may cause ulceration or irritation of the G.I. tract. Therefore, do not give in active peptic ulcer, gastritis, regional enteritis, ulcerative colitis, and use with caution if there is a history of these disorders.

For additional prescribing information, please see following page.

In selected cases
of rheumatoid arthritis
with acute symptoms

Response to INDOCIN® (Indomethacin | MSD) is often improved by stepping up dosage daily until a satisfactory result is obtained



IMPORTANT NOTE: INDOCIN (Indomethacin, MSD) cannot be considered a simple analgesic and should not be used in conditions other than those recommended under Indications. The drug should not be prescribed for children because safe conditions for use have not been established.

Indications: For the symptomatic treatment of rheumatoid arthritis, rheumatoid (ankylosing) spondylitis, degenerative joint disease (osteoarthritis) of the hip, and gout.

Contraindications: INDOCIN may mask the signs and symptoms of peptic ulcer and may itself cause peptic ulceration or irritation of the G.I. tract. For these reasons it should not be given to patients with active peptic ulcer, gastritis, regional enteritis, or ulcerative colitis (use with caution if there is history of these disorders); aspirin-sensitive asthmatics. Safe use during pregnancy or during lactation has not been established. Should not be prescribed for children because safe conditions for use have not been established. In a few cases of severe juvenile rheumatoid arthritis receiving INDOCIN along with other drugs, severe reactions, including fatalities, have been reported.

Warnings: Patients who experience dizziness, lightheadedness, or feelings of detachment on INDOCIN should be cautioned against operating motor vehicles or machinery, climbing ladders, etc. Use cautiously in patients with psychiatric disturbances, epilepsy, or parkinsonism since it may aggravate these conditions.

Precautions: Use cautiously in patients with a history of peptic ulcer, gastritis, regional ileitis, or ulcerative colitis because of its potential for causing G.I. bleeding. May cause single or multiple ulceration of the esophagus, stomach, duodenum, or small intestine, and, in a few instances, severe bleeding and perforation with a few fatalities have been reported. May potentiate the ulcerogenic effect of steroids, salicylates, or phenylbutazone. Gastrointestinal bleeding with no obvious ulcer formation has also been noted; the drug should be discontinued if G.I. bleeding occurs. As a result of obvious or occult G.I. bleeding, some patients may manifest anemia, and for this reason periodic hemoglobin determinations are recommended. G.I. effects may be minimized by giving the drug with food or with antacids or immediately after meals. In common with other drugs that have anti-inflammatory, analgesic, and antipyretic properties, indomethacin may mask the signs and symptoms of infection; avoid undue delay in initiating appropriate treatment of the infection; use cautiously in patients with existing, but controlled, infections. As with any new drug, patients should be followed carefully to detect unusual manifestations of drug sensitivity.

Adverse Reactions: Starting therapy with low doses, with gradual increases when necessary, will minimize adverse reactions. *Central Nervous System:* Most commonly, headache (usually more severe in morning), dizziness, and lightheadedness; infrequently observed reactions include mental confusion, drowsiness, convulsions, coma, depression, and other psychic disturbances, such as depersonalization; CNS effects are often transient and frequently disappear with continued treatment or reduced dosage. The severity of these effects may occasionally require cessation of therapy. *Gastrointestinal:* Most commonly, nausea, anorexia, vomiting, epigastric distress, abdominal pain, and diarrhea; others that may develop are ulceration, single or multiple, of esophagus, stomach, duodenum, or small intestine, including perforation and hemorrhage with a few fatalities having been reported; G.I. bleeding without obvious ulcer formation, increased abdominal pain in patients with preexisting ulcerative colitis; less commonly, stomatitis; gastritis; bleeding from the sigmoid colon, occult in type or from a diverticulum, and perforation of preexisting sigmoid lesions (diverticulum, carcinoma); G.I. reactions not known definitely to be attributable to indomethacin include development of ulcerative colitis and of regional ileitis. *Hepatic:* Rarely, jaundice and hepatitis. *Cardiovascular-Renal:* Infrequently, edema, elevation of blood pressure, and hematuria. *Dermatologic-Hypersensitivity:* Infrequently, pruritus, urticaria, angioneurotic edema, angiitis, skin rashes, loss of hair, and acute respiratory distress including sudden dyspnea and asthma. *Hematologic:* Infrequently, leukopenia, purpura, and thrombocytopenia; rarely, agranulocytosis and bone marrow depression have been reported, but a definite relationship to the drug has not been established; since some patients may manifest anemia secondary to obvious or occult G.I. bleeding, periodic hemoglobin determinations are recommended. *Eye-Ear:* Infrequently, tinnitus, blurred vision, hearing disturbance, and orbital and periorbital pain. *Miscellaneous:* Rarely, vaginal bleeding, hyperglycemia, and glycosuria.

Supplied: Capsules containing 25 mg indomethacin each, in bottles of 100 and 1000; capsules containing 50 mg indomethacin each, in bottles of 100.

WHERE TODAY'S THEORY IS TOMORROW'S THERAPY

Diagnostic Problem

Subinguinal Varix*

THE SUBINGUINAL VARIX sometimes presents a problem of diagnosis and treatment because it is easily misdiagnosed as a femoral hernia from the similarity in location, size, and globular appearance. Other protruding masses in the groin must be included in the differential diagnosis of this venous tumor. A correct diagnosis is essential, since otherwise the preparation will not be adequate for operation on varicose veins.

Many patients with this globular varix in the groin have been examined during the past two decades in the Section of Peripheral Vein Surgery of the Mayo Clinic. Quite often the initial diagnosis made by a resident or consultant was femoral hernia.

Anatomy

The anatomic relationships in the femoral (Scarpa's) triangle must be kept in mind when examining protruding masses in the groin. This triangle is bounded superiorly by the inguinal ligament, laterally by the sartorius muscle, and medially by the adductor longus muscle. Important structures within it are the femoral canal, femoral vein and artery, and femoral nerve, all invested by the femoral sheath. The great saphenous vein originates from the femoral vein, emerges through the fossa ovalis just below the inguinal ligament, and courses diagonally downward and medially over the inner thigh and leg. The femoral canal terminates in the fossa ovalis; thus a large femoral hernia protrudes through this aperture and appears also as a bulging mass in the same location as a subinguinal varix. The triangle also contains numerous subinguinal lymph nodes which are usually small and insignificant.

Differential Diagnosis

The subinguinal varix must be differentiated from other protruding masses in the groin, the most common of which is femoral hernia. This varix is a peculiar, saccular dilatation of a very short proximal segment of the great saphenous vein, just distal to its origin from the femoral vein but superficial to the fossa ovalis and femoral sheath. This proximal portion of the saphenous vein is not only poorly supported by surrounding tissues but also exposed to high venous pressures caused by increased intra-abdominal pressure during coughing, straining, or lifting.

A femoral hernia protrudes from the intra-abdominal space downward into and through the femoral canal and then courses laterally and outward along the path of least resistance until it protrudes through the fossa ovalis along with the great saphenous vein. The sac of the femoral hernia may be small and is often preceded by a large amount of extraperitoneal fat. The protruding mass may thus appear as an elongated, elastic swelling of considerable size. The sac often contains an omental tag, and the hernia is seldom more than partially reducible into the femoral canal. Femoral hernia, which is always acquired (in contrast to inguinal hernia), occurs more frequently in females than in males (three to four times more commonly), probably because of the greater proportional width of the pelvis and the greater size of the femoral ring. The small neck of a large femoral hernia protrudes *below* the inguinal ligament through the fossa ovalis, whereas the neck of an inguinal hernia protrudes *above* the ligament.

---

*Read at the meeting of the Southern Minnesota Medical Association, Owatonna, September 20, 1968.

Other protruding masses in the groin, though less likely to be confused with the saphenous varix but still included in the differential diagnosis, are a solitary enlarged lymph node, a lipoma, a hydrocele of the spermatic cord or of the canal of Nuck, and an undescended testicle. An enlarged lymph node is firm and irreducible, tender when inflamed, and usually associated with a recent infection of the regional skin or subcutaneous tissues. A lipoma is soft, nontender, and freely movable on palpation. A hydrocele will transilluminate, and its location is typically above and medial to the pubic spine, along the course of the spermatic cord in the male, or the canal of Nuck in the female. An undescended testicle has a similar location in the male.

Diagnosis

The diagnosis of a subinguinal varix is based on (1) its location—just below and superficial to the fossa ovalis; (2) its reducibility—prompt on finger pressure or on change from standing to reclining posture; (3) its association with other varicosities in the lower limb; and (4) its transmission of a venous impulse along the course of the great saphenous vein—a characteristic and most helpful finding.

The transmission of the venous impulse is the most significant diagnostic finding. This test is performed by quickly compressing the varix in the groin with the fingers of one hand and palpating the transmitted impulse along the course of the great saphenous vein by the fingers of the other hand, just above the inner aspect of the knee. The venous impulse can likewise be transmitted upward into the subinguinal varix by quickly compressing the saphenous vein below. This particular test *conclusively* differentiates a saphenous varix from a femoral hernia. The cough impulse occurs with either a varix or a hernia and is therefore not a reliable test in the differential diagnosis. The transmission of a venous impulse does *not* occur with other protruding masses in the groin. A case is illustrated in the Figure.

Observations in 10 Cases

Many patients who were operated on for varicose veins during the past two decades had groin lesions varying from a minimal local dilatation to a round mass with a diameter of 5 or 6 cm. Ten patients were selected for review because their groin lesions had a confusing resemblance to femoral hernia. In

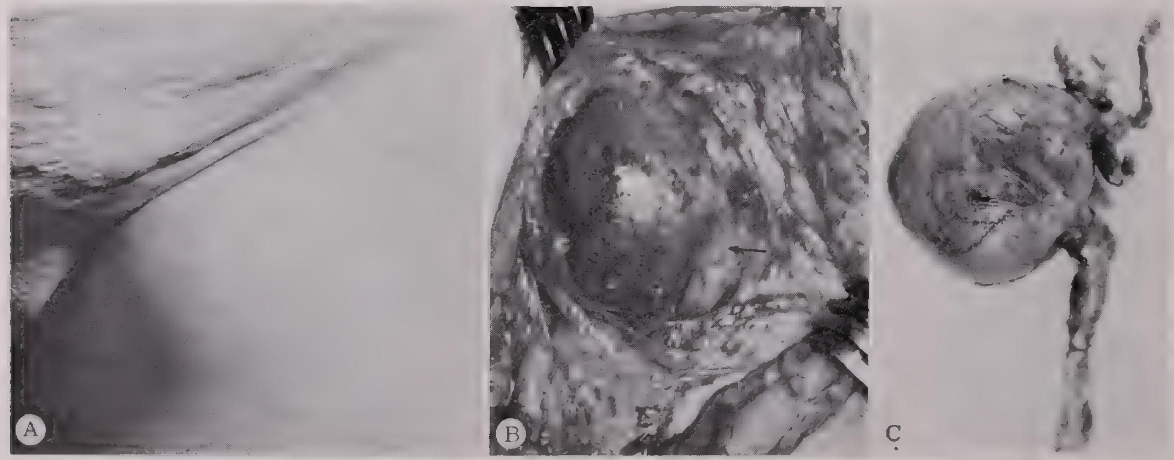

Figure: Subinguinal varix in left groin. *A*, Clinical appearance. *B*, Exposure of varix in groin incision. Arrow indicates great saphenous vein. *C*, Surgical specimen showing round varix 4 cm in diameter.

all, the onset had been insidious and without acute pain. The clinical diagnosis on initial examination was femoral hernia (incorrect) in five cases and saphenous varix (correct) in five. The globular varix was situated in the right groin in five patients and in the left groin in four, and one patient had a round mass in each groin. Eight patients were women and two were men. Their ages ranged from 30 to 74 years. All had associated incompetency of the great saphenous vein in one or both legs.

Summary

1. The subinguinal varix is easily mistaken for a femoral hernia because of similarity in location, size, and appearance.
2. It is promptly reduced by finger pressure or by change from a standing to a reclining posture, and it is usually associated with other varicosities in the leg.
3. Transmission of a venous impulse is characteristic and confirms the diagnosis of subinguinal varix.
4. The treatment is surgical removal of the subinguinal varix and of the incompetent great saphenous system from the foot to the saphenofemoral juncture.

Shakespeare: Diseases

Epilepsy

Among Shakespeare's repertoire of dramatic stage devices, epilepsy furnishes two sensational examples: one in *Othello,* another in *Julius Caesar.*

Listening in on Iago's and Cassio's dialogue we hear:

Iago: How now, Cassio!
Cassio: What's the matter?
Iago: My lord is fallen into an epilepsy:
This is his second fit; he had one yesterday.
Cassio: Rub him about the temples.
Iago: No, forbear;
The lethargy must have his quiet course:
If not, he foams at mouth, and by-and-by
Breaks out to savage madness. Look, he stirs:
Do you withdraw yourself a little while;
He will recover straight.*

Joining Brutus, Cassius, and Casca in a public square in Rome we overhear:

Cassius: What, did Caesar swoon?
Casca: He fell down in the market-place, and foamed at mouth, and was speechless.
Brutus: 'Tis very like: he hath the falling-sickness.
Casca: When he came to himself again he said, if he had done or said anything amiss, he desired their Worships to think it was his infirmity.†

---

*Othello: IV, 1
†Julius Caesar: I, 2

Convalescing . . . but still a long way to go. Anxiety can make it even longer.

Convalescence following medical or surgical procedures may be almost endless to an anxious patient. And, indeed, anxiety with some patients actually retards progress—for example, by inducing insomnia and reducing cooperation.

As physicians have found during nearly 15 years of widespread use, Equanil may be a beneficial part of aftercare. It helps relieve anxiety and tension, thus often aiding your primary therapy.

Indications: For use in management of anxiety and tension occurring alone or as accompanying symptom complex to medical and surgical disorders and procedures. Though not a hypnotic, fosters normal sleep through antianxiety and related muscle-relaxant properties.

Contraindications: History of sensitivity to meprobamate.

Important Precautions: Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use has been reported to result in dependence or habituation in susceptible persons, as alcoholics, ex-addicts, and other severe psychoneurotics. After prolonged excessive dosage, reduce dosage gradually to avoid possibly severe withdrawal reactions. Abrupt discontinuance of excessive doses has sometimes resulted in epileptiform seizures.

Warn patients of possible reduced alcohol tolerance, with resultant slowing of reaction time and impairment of judgment and coordination.

Reduce dose if drowsiness, ataxia or visual disturbance occurs; if persistent, patients should not operate vehicles or dangerous machinery.

Side Effects include drowsiness, usually transient; if persistent and associated with ataxia, usually responds to dose reduction; occasionally concomitant CNS stimulants (amphetamine, mephentermine sulfate) are desirable. Allergic or idiosyncratic reactions are rare, but such reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Previous history of allergy may or may not be related to incidence of reactions. Mild reactions are characterized by itchy urticarial or erythematous maculopapular rash, generalized or confined to groin. Acute nonthrombocytopenic purpura with cutaneous petechiae, ecchymoses, peripheral edema and fever have been reported. One fatal case of bullous dermatitis following intermittent use of meprobamate with prednisolone has been reported. If allergic reaction occurs, meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioneurotic edema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. Treat symptomatically as with epinephrine, antihistamine and possibly hydrocortisone. Aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis and hemolytic anemia have occurred rarely, almost always in presence of known toxic agents. A few cases of leukopenia, usually transient, have been reported on continuous administration.

Meprobamate may sometimes precipitate grand mal attacks in patients susceptible to both grand and petit mal. Extremely large doses can produce rhythmic fast activity in the cortical pattern. Impairment of accommodation and visual acuity has been reported rarely. After excessive dosage for weeks or months, withdraw gradually (1 or 2 weeks) to avoid recurrence of pretreatment symptoms (insomnia, severe anxiety, anorexia). Abrupt discontinuance of excessive doses has sometimes resulted in vomiting, ataxia, tremors, muscle twitching and epileptiform seizures. Prescribe very cautiously and in small amounts for patients with suicidal tendencies. Suicidal attempts have resulted in coma, shock, vasomotor and respiratory collapse and anuria. Excessive doses have resulted in prompt sleep; reduction of blood pressure, pulse and respiratory rates to basal levels; and occasionally hyperventilation. Treat with immediate gastric lavage and appropriate symptomatic therapy. (CNS stimulants and pressor amines as indicated.) Doses above 2400 mg./day are not recommended.

Composition: Tablets, 200 mg. and 400 mg. meprobamate. Coated Tablets, WYSEALS® EQUANIL (meprobamate) 400 mg. (All tablets also available in REDIPAK® [strip pack], Wyeth.) Continuous-Release Capsules, EQUANIL L-A (meprobamate) 400 mg.

Abstracts, Briefs and Commentaries

EMPYEMA OF THE THORAX IN ADULTS

Thoracic empyema has become an uncommon disease in adults tending to occur in chronically ill individuals. In this series of 105 cases, underlying pneumonia was the cause of the empyema in more than half the cases. Empyema resulted from prior thoracic surgery in almost one quarter of all cases. Staphylococcus aureus and gram-negative bacilli were the most commonly found organisms. Successful therapy is founded on correct choice and adequate dose of antibiotics, prompt institution of adequate drainage and recognition and treatment of underlying factors. Chronic cases of empyema were treated by decortication, pulmonary resection and thoracoplasty. Mortality was less than five percent from the empyema.

TREATMENT OF HYPERTENSION

A follow-up study of 97 hypertensive patients with group 3 hypertension (or retinopathy) and 64 patients with malignant (group 4) hypertension clearly demonstrated that medical treatment improves the prognosis, although the mortality rate remained disappointingly high. The five-year survival rate was 37.5% for patients with group 3 retinopathy and 28.6% for patients with malignant hypertension. Inadequate control of blood pressure, cessation of therapy, short duration of hypertension, and significant azotemia were associated with worse-than-average mortality rates. Effective treatment not only prolonged life but led to the regression of retinal hemorrhages, exudates and papilledema; but control of the hypertension did not seem to influence favorably those complications that are due to atherosclerosis, especially cerebrovascular accident. More than 10% of the survivors suffered cerebral vascular accidents, and this complication was the leading cause of death in this series. The marked relationship found between the degree of control of hypertension and longer survival suggests that more effective and better tolerated drugs will further improve the prognosis in severe hypertension.

PERFORATION OF RIGHT VENTRICULAR WALL BY THE ENDOCARDIAL PACING CATHETER

Four clinically documented cases of the right ventricular wall perforation, due to a hard-tipped intravenous pacemaker catheter are presented. One patient expired. The cause of death was pericardial tamponade caused by the hemorrhage into the pericardium through the perforation. The other three cases were found at the time of thoracotomy but resulted in no detectable complication. Use of soft-tipped pacing catheters, along with careful manipulation under fluoroscopic guidance, should lessen the chance of myocardial perforation in cases of intravenous pacemaker implantation. The cases of perforation of the myocardium were all in patients in whom a pacing catheter had been used.

GASTRIC LYMPHOMA

Two pathologists made a retrospective survey of 71 patients with gastric lymphoma. At the time of diagnosis 65 patients had primary gastric tumors and six cases were associated with diffuse disease. Most patients had less than six months of symptoms. The five-year and ten-year survival rates for primary lesions were 59 and 28 percent. The best prognosis occurred with small, superficial lesions confined to the stomach. In long-term survivals, lymphoma of the stomach is not necessarily a manifestation of systemic disease.

PREVENTION OF RECURRENT PULMONARY EMBOLI WITH ANTICOAGULANTS

This resume of treatment of 704 patients with pulmonary thrombo-embolism leads to the conclusion that oral anticoagulants are beneficial. In treated patients, if the Quick one-stage prothrombin time was more than 1.6 times control, the rate of recurrent pulmonary embolism was reduced to 2 percent. A higher incidence (10.4 percent) was reported in patients for whom therapy was inadequate (prothrombin time less than 1.6 times control value). No mention was made of ligation or plication of vena cava in this large series of patients.

MALIGNANT MELANOMA OF THE PENIS

The authors were able to collect only 23 published reports on melanoma of the penis with a world-wide distribution. Wattenberg collected only eleven reported cases in 1944. Ten cases ranged from 48 to 78 years of age. Nine occurred on the glans and one on the prepuce; seven had secondary deposits when first seen. Four more were reported by MacDermott and Kennedy in 1955. Abeshouse and Goldstein collected 18 cases in 1962. Buddington Kitckham and Smith in 1963 found only one melanoma in 104 consecutive primary malignancies of this organ. Gupta and Grabstald in 1965, in no less than 1200 malignant melanomas, found only one involving the penis.

Case Report

A 44-year-old male was admitted to Westminster Hospital, London, in 1966. Twelve months previously he had noticed a black spot on the under side of his glans penis. One month before admission he had noted superficial ulceration and slight bleeding. He was unmarried, had been circumcised in infancy and had no history of venereal disease. Examination of the glans revealed grey-black spots, flat, with the same consistency as the surrounding area. The ulcerated point was near the urethral orifice 0.5 cm. in diameter in a pigmented zone.

Physical examination was negative; biopsy consisting of a partial amputation revealed a malignant melanoma. Amputation proximal to the glans proved to be well below the growth.

Treatment—Lugols solution 10 minims was given three times daily for three days. A vessel on the right side of the shaft near its base was cannulated. Lipiodol with ^{131}I was injected under pressure to extravasate around the lymphatics. Radiographs showed that nodes in the left groin had filled and that there was some extravasation deep to the skin covering the penis. No vessel being available on the right side of the penis a right pedal vessel was cannulated and additional ^{131}I in lipiodol was injected.

Lymphograms showed good filling of the lymph nodes in the inguinal, iliac and lower para-aortic nodes on the right and iliac and lower para-aortic nodes on the left. The thyroid showed no uptake.

Progress: Twenty-one months from the date of operation the patient is well, free from clinical recurrence with normal chest x-rays. There has been moderate edema of the right leg and two episodes of erysipelas-like infection.

Discussion

Melanoma of the penis is rare and the effects of various types of treatment are scant, with only two long-time survivals. Invasion of inguinal lymph nodes is grave. Radiotherapy is of doubtful value. Management of regional nodes can be expectant only, or comprise active therapy by bilateral block dissection or by endolymphatic therapy using radioactive material.

The endolymphatic therapy using radioactive gold produces destruction of lymphatic vessels and nodes not suitable for surgical ablation. Since the development of ^{131}I lipiodol the same result is accomplished with less extravasation.

Controlled Oxygen Administration in Respiratory Failure

DAVID E. DINES, M.D.*
JUI-SUNG HUNG, M.D.†
WILLIAM F. REILLY, JR., M.D.†
RICHARD A. WILLSON, M.D.†
Rochester, Minnesota

THE RELENTLESS RISE in the incidence of chronic obstructive pulmonary disease has demanded that physicians become familiar with the basic management of acute respiratory failure. It is well known that controlled oxygen in respiratory failure should be aimed at correcting the hypoxia to a safe level without enhancing the respiratory acidosis.

Barach[1] introduced the concept of regulated oxygen therapy by the use of low flow rates of oxygen in 1938, but the importance of the concept of correcting the hypoxia was not appreciated until Campbell[2,3] in 1960 and Massaro and associates[4] and Kory and co-workers[5] in 1962 made comparative evaluations of oxygen therapy in respiratory failure.

In addition to the necessity for low concentration of oxygen, the manner in which it is delivered is exceedingly important. In 1954 Cohn and associates[6] recommended the intermittent administration of oxygen, with short periods of air breathing, for patients with acute carbon dioxide retention. Campbell[7] pointed out that intermittent administration of oxygen may produce more deleterious effects, as the depressant action persists for some time after the oxygen has been withdrawn and may result in more severe hypoxia than existed before the oxygen was administered. This occurs because a decrease in the concentration of oxygen in the inspired air results in an immediate change in arterial oxygen concentration; the change is immediate because of the small stores of oxygen in the body.

Kory and associates[5] and Barach[8] found that adequate inspired concentrations of oxygen could be achieved with nasal cannula. Conversely, Longobardi and co-workers[9] concluded that only insufflation of oxygen into the oropharynx by catheter gave reliable concentrations of oxygen. Cherniack and Hakimpour[10] have advocated low flow rates through nasal cannula at 2 to 3 liters/min, and they have demonstrated correction of arterial hypoxia with 2 to 3 liters/min and no further hypercapnia.‡ Campbell and Gebbie[11] stated the belief that the level of inspired oxygen concentration is critical in respiratory failure because of the possibility of precipitating further retention of carbon dioxide and have recommended the "Ventimask," a plastic disposable mask that operates on the Venturi principle. Schiff and Massaro[12] have found this type of mask preferable to the nasal catheter for oxygen administration. Mithoefer and associates[13] found that the Ventimask at 24, 28, and 35% frequently failed to correct hypoxia to a safe level, and 24% of the patients receiving 35% oxygen had oxygen tensions below 50 mm Hg.

The necessity of lessening hypoxemia during acute respiratory failure in patients with chronic obstructive pulmonary disease is well accepted. Oxygen therapy in an uncontrolled fashion may lead to deterioration of ventilation, increased acidosis, and occasionally coma.

‡See Test Your Word Score Page 933.

Controlled, low concentrations of inspired oxygen have been devised by Campbell and Gebbie,[11] utilizing a plastic disposable mask (Figure) specifically designed to deliver 24, 28, or 35% oxygen. Four liters/min are delivered with the 24 and 28% Ventimask and 8 liters/min with the 35% Ventimask. The masks are perforated to provide known concentrations of 24, 28, or 35% oxygen.

Four patients with chronic obstructive pulmonary disease are presented to show what happens to the arterial oxygen tension (Pa_{O_2}), arterial carbon dioxide tension (Pa_{CO_2}), and pH, when oxygen is administered to patients with pulmonary insufficiency. A comparison also has been made between oxygen administered by Ventimask and oxygen administered by nasal cannula in two of the patients with pulmonary insufficiency.

Report of Cases

Case 1

A 68-year-old mechanic with known chronic obstructive pulmonary disease was admitted to the hospital on December 5, 1967, because of increased shortness of breath.

On examination he was cyanotic at rest and tachypneic (respiration rate 28/min). There was expiratory slowing of grade 3, and the pulmonary closure sound was accentuated.

The hemoglobin value was 15 gm/100 ml of serum, and the hematocrit reading was 56%. The electrocardiogram showed a prominent P wave in lead II, right axis deviation, and a right ventricular conduction delay. A chest roentgenogram showed prominent pulmonary artery segments bilaterally and hyperlucency of the lungs at both bases. Pulmonary function tests had not been done since 1960; at that time these showed an obstructive pattern with the ratio of residual volume to total capacity elevated to 73%, a maximal breathing capacity of 35 liters/min, expiratory slowing of grade 4, elevation of the nitrogen washout to 6.0%, and a resting arterial oxygen saturation of 86%.

Arterial blood gas values are listed in the Table.

The patient was treated with low-flow oxygen at 2 liters/min, intermittent positive pressure, bronchodilators, sodium restriction, expectorants, and digitalis. Diuresis resulted in loss of 17 pounds in two weeks.

Comment

This is an example of a patient with chronic obstructive pulmonary disease, emphysema, and chronic bronchitis, who was hypoxic at rest (arterial oxygen tension, 44 mm Hg). He was given oxygen by nasal cannula at 2 liters/min, and the arterial oxygen tension increased to 60 mm Hg, with only a slight rise in the arterial carbon dioxide tension to 63 mm Hg. The arterial oxygen tension of 60 mm Hg was in a safe range, which shows the effectiveness of controlled, low-flow oxygen at 2 liters/min by nasal cannula.

Next, the 24% Ventimask was utilized, and the arterial oxygen tension was increased to 55 mm Hg, a safe level but not as high as achieved with nasal cannula at 2 liters/min.

The 28% Ventimask increased the arterial oxygen tension to 96 mm Hg, but with a dangerous rise in the arterial carbon dioxide tension to 80 mm Hg and a drop in pH to 7.27.

Case 2

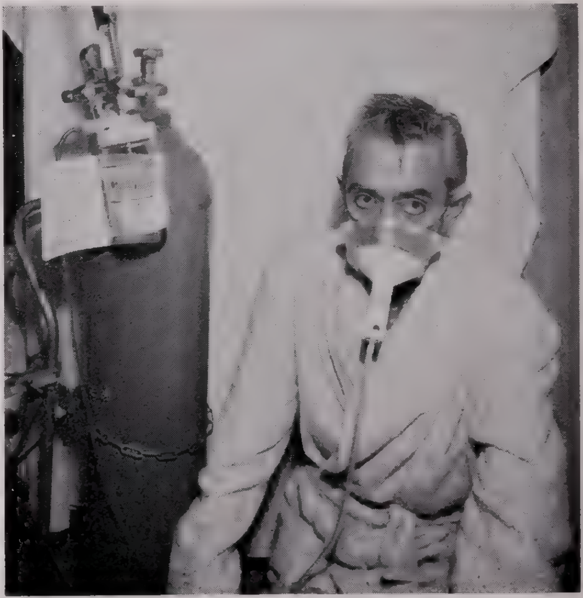
A 53-year-old cattle inspector was admitted to the hospital on November 13, 1967, with productive cough, shortness of breath, orthopnea, and ankle edema.

On admission he was cyanotic, tachypneic, and orthopneic, with hyperresonance to percussion, rales at both bases, scattered rhonchi and wheezes, and expiratory slowing of grade 3.

The hemoglobin value was 16 gm/100 ml of serum, and the hematocrit reading was 59%. The electrocardiogram revealed right axis deviation with enlargement of the right atrium and right ventricle. A chest roentgenogram showed prominent pulmonary artery segments and vascular congestion. Pulmonary function, performed after diuresis, revealed an obstructive pattern with a maximal breathing capacity of 30 liters/min, a maximal midexpiratory flow rate of 0.4 liters/sec, a nitrogen washout of 6.9%, and an arterial oxygen desaturation to 79% at rest. A carbon monoxide diffusing capacity was 5 ml/min/mm Hg (normal 22).

Arterial blood gas values are listed in the Table.

The patient was treated with low-flow oxygen using the 28% Ventimask, intermittent positive pressure, bron-



Figure

Example of disposable plastic mask used in delivery of controlled, low concentrations of inspired oxygen.

chodilators, expectorants, and diuretics; and he was slowly digitalized. Diuresis resulted in a loss of 30 pounds while in the hospital. Two pints of blood were removed on successive days to decrease the hematocrit level to 54%.

Comment

The second patient has severe chronic obstructive pulmonary disease with chronic bronchitis, emphysema, cor pulmonale, congestive failure, profound hypoxia, and hypercapnia. The arterial oxygen tension was 31 mm Hg at room air. On two successive days, oxygen by nasal cannula at 2 liters/min increased the arterial oxygen tension to only 37 and 39 mm Hg, respectively. The 24% Ventimask increased the arterial oxygen tension to 47 mm Hg, but still the level was not in a safe range. The 28% Ventimask increased the arterial oxygen tension to 62 mm Hg without further hypercapnia. Because oxygen saturation of 90% was achieved with the 28% Ventimask, there was no consideration of using the 35% Ventimask, which would only lead to further hypercapnia to the level of narcosis.

Case 3

A 58-year-old white man was admitted because of a 10-year history of shortness of breath.

On examination he was plethoric and cyanotic and had expiratory slowing of grade 4.

The hemoglobin value was 17.8 gm/100 ml of serum, and the hematocrit value was 59%. Pulmonary function showed an obstructive pattern with a maximal breathing capacity of 68 liters/min (estimated normal for this patient, 120), a maximal midexpiratory flow rate of 0.8 liters/sec, and a nitrogen washout of 4.2%. The arterial oxygen saturation was 95% at rest. A chest roentgenogram was suggestive of hyperaeration, with prominent pulmonary artery segments. The electrocardiogram showed only a right axis deviation.

Values for arterial blood gas tension are listed in the Table.

Comment

Case 3 is included to show how oxygen saturation from ear oximetry* may not give the true picture. Patient 3 had chronic obstructive pulmonary disease with emphysema and chronic bronchitis, mild secondary polycythemia, and a low arterial oxygen tension (65 mm Hg). This case illustrates that hypoxemia in chronic obstructive pulmonary disease may occur with or without hypercapnia. Therapy with low-flow oxygen using nasal cannula at 2 liters/min increased the arterial oxygen tension to 84 mm Hg without a dangerous rise in the arterial carbon dioxide tension. The 24% Ventimask would give the same results. Oxygen was administered by nasal cannula at 2 liters/min to show that low-flow oxygen can be given safely without affecting the arterial carbon dioxide tension.

Case 4

A 55-year-old man was admitted to the hospital on February 28, 1968, profoundly dyspneic, with a known diagnosis of chronic obstructive pulmonary disease, chronic bronchitis, bronchiectasis, and cor pulmonale. He was in right ventricular failure; he had bronchopneumonia with fever, cough, and purulent sputum; he was hypoxic, hypercapneic, and polycythemic. A chest roentgenogram showed honeycombing in both bases, pulmonary vascular congestion, bullous changes in both upper lobes, and prominent pulmonary artery segments indicative of cor pulmonale. Pulmonary function, performed at a time when he was not in failure, showed an obstructive pattern with a high nitrogen washout index of 11.9% (normal less than 2.5) and arterial oxygen desaturation.

On admission, he had an arterial oxygen tension of 35 mm Hg and an arterial carbon dioxide tension of 56 mm Hg with an arterial pH of 7.26 (Table). He was given low-flow oxygen by nasal cannula at 2 liters/min, along with intermittent positive-pressure breathing, aminophylline, expectorants, and broad-spectrum antibiotics. A phlebotomy was performed, and he was given 1.0 mg of digoxin. Seven hours later, the arterial oxygen tension was 59 mm Hg, but the arterial carbon dioxide tension had risen to 92 mm Hg and the pH had dropped to 7.14. Assisted ventilation became necessary with an oral tracheal tube and a Bird valve. Twenty-four hours later the arterial oxygen tension was 97 mm Hg, the arterial carbon dioxide tension 57 mm Hg, and the pH 7.30 (Table).

Comment

This is an example of a patient with chronic obstructive pulmonary disease, chronic bronchitis, bronchiectasis, cor pulmonale, and right ventricular failure, in whom low-flow oxygen by nasal cannula was not successful because of the severe secretion problem, pneumonitis, and superimposed pulmonary congestion. An oral tracheal tube and assisted ventilation became necessary. It does show the importance of adequate monitoring with arterial blood gases, and how mandatory it is to intubate and assist ventilation in the face of a rising arterial carbon dioxide tension while low-flow oxygen is being administered.

Discussion

Arterial hypoxia, resulting from respiratory failure, can be relieved by increasing either the effectiveness of the ventilation or the concentration of inspired oxygen. Hypoxia develops from inefficiency of the diseased lung to deliver oxygen from the ambient air to the arterial blood. The effect of an increase in the inspired oxygen concentration on the arterial oxygen tension depends on the severity of the diseased lung. Hypoxemia in chronic obstructive pulmonary disease may occur with or without hypercapnia. Acute respiratory failure with hypoxemia necessitates oxygen supplementation; controlled oxygen therapy can be achieved with nasal cannula at 2 liters/min or with the Ventimask at 24% and 28%. Adequate monitoring is essential, as therapy with uncontrolled oxygen may seriously worsen ventilation. It has been shown that even a mildly elevated arterial carbon dioxide tension does not ensure against oxygen-induced hypoventilation.[14] An arterial oxygen tension of 50 mm Hg has been accepted as the minimal goal of oxygen therapy.[15] Both the nasal cannula and the Ventimask are well accepted by the patient. One disadvantage of the mask is that its use has to be interrupted for feeding and nebulization therapy.

---

*See Test Your Word Score Page 933.

Oxygen therapy is obviously required. We must be aware of the potential risk of oxygen-induced hypoventilation. Hypoxemia may be severe from hypoventilation and also from venous admixture resulting from the pulmonary disease.

Effective management of oxygen therapy requires careful measurements of arterial oxygen tensions. In some cases the nasal cannula will be more helpful and in others the Ventimask. In still others, therapy with 100% oxygen may not result in an arterial oxygen saturation that is sufficient for function or survival.

Summary

Arterial hypoxia resulting from respiratory failure can be relieved by increasing the effectiveness of ventilation or the concentration of inspired oxygen.

Oxygen therapy in respiratory failure should be aimed at correcting the hypoxia to a safe

TABLE

Arterial Blood Gas Values in Chronic Obstructive Pulmonary Disease and Respiratory Failure

Case	Pa_{O_2}, mm Hg	Pa_{CO_2}, mm Hg	pH	O_2 saturation, %	Condition
1	44	56	7.41	80	Room air
	60	62	7.33	89	Nasal cannula, 2 L/min
	55	63	7.33	86	Ventimask, 24%
	96	80	7.27	96	Ventimask, 28%
	54	74	7.34	85	Ventimask, 24%
	59	73	7.35	89	Nasal cannula, 2 L/min
2	31	55	7.44	62	Room air
	37	52	7.43	72	Nasal cannula, 2 L/min
	39	60	7.40	73	Nasal cannula, 2 L/min
	47	60	7.38	82	Ventimask, 24%
	62	68	7.34	90	Ventimask, 28%
	62	62	7.39	92	Ventimask, 28%
3	65	38	7.47	94	Room air
	84	44	7.44	97	Nasal cannula, 2 L/min
4	35	56	7.26	57.5	On admission
	59	92	7.14	79	Nasal cannula, 2 L/min (7 hr later)
	97	57	7.30	96	Oral tracheal tube and controlled on Bird respirator (24 hr later)

level without enhancing the respiratory acidosis.

Two cases are presented to show the beneficial effects of controlled, low-flow oxygen by nasal cannula at 2 liters/min and by Ventimask at 24% and 28%. Both methods are effective in the administration of controlled, low-flow oxygen.

The third case illustrates how oxygen saturations from ear oximetry may not give a true picture in some patients and how controlled low-flow oxygen can be administered safely without the danger of hypercapnia. It also shows that hypoxemia may occur in chronic obstructive pulmonary disease without hypercapnia.

The fourth case is an example of low-flow oxygen being unsuccessful in relieving the hypoxemia because of a secretion problem, pneumonitis, and superimposed pulmonary congestion.

Time

Here are the results of a survey conducted by a psychology class at the University of Wisconsin. If you live to be seventy or over, chances are that you will spend at least twenty years asleep. Two hours of your life will be taken up just punching a time clock or signing a time sheet for the twenty-five solid years of work you will do.

Golf, bowling and hiking will probably take up some of the seven years you are allowed for sports and walking. For five years you will shave and dress, and spend five months tying your shoes. Of the six-hundred-and-thirteen-thousand hours in your lifetime, a few over four thousand are allowed for playing cards. For seven years you will go to the movies, theater or other amusements. Another year will be spent at the telephone.

For two and a half years you will sit at a table, eating, and for another two and a half years you will smoke or chew gum.

The seventy-year life span includes three years of waiting, thirty hours annually looking in mirrors, and just for the record, you are allowed four hours a year for wiping your nose.

—Marion Pehowski, Journal of Living

Technique

Protocol for Cope Needle Pleural Biopsy*

Pleural biopsy should be considered in every patient with a pleural effusion in whom the cause is not apparent. This would exclude pleural biopsy when the effusion occurred as part of the clinical picture of congestive failure, cirrhosis, nephrosis, pneumonia, pulmonary embolus/infarct, collagen disease, and trauma to the involved hemithorax. The histologic picture tends to be non-specific in these conditions and no useful purpose is served by pleural biopsy. However, if the pleural fluid obtained on thoracentesis has the characteristics of an exudate (protein concentration of greater than 2.5 gm. %) when a transudate was expected, e.g., in congestive heart failure, a pleural biopsy should be performed as a primary diagnostic procedure at the time of initial thoracentesis. Lack of pleural effusion is not an absolute contraindication to performance of a pleural biopsy, but it does call for experienced personnel familiar with the technique.

Pre-Biopsy Workup

Roentgenologic

PA and lateral chest films are usually adequate and should be done within 24 hours of the biopsy. If the effusion is small or localized, obliques may be helpful.

Fluoroscopy may be necessary with small effusions and should be utilized freely with placement of markers to ascertain the most desirable biopsy site.

Hematology

History of bleeding tendency or recent administration of anticoagulant medications must be sought. Prothrombin time, bleeding and clotting time should be obtained, and occasionally platelet counts may be necessary.

Pre-medication

Barbiturates, depending upon the age and respiratory status of the patient, are advisable, since local anesthetics will be used.

Atropine, in a dose of 0.3 to 0.4 mg., should be given subcutaneously unless there is a specific contraindication. Atropine serves to prevent pleural shock, which is believed to be a vagal reaction.

Equipment, Materials

Preparation tray, medical thoracentesis tray and Cope biopsy needle are obtained; 1% Lidocaine, specimen jar with formalin, bottle with alcohol for cell block, and tube of culture medium should be at hand.

Position of Patient

This is usually sitting with arms and head supported against the examining table or bed; the patient must be comfortable. Localization of the effusion by physical diagnostic means should be done at this time. If there is any question as to the proper interspace, preference should be given to the upper one.

---

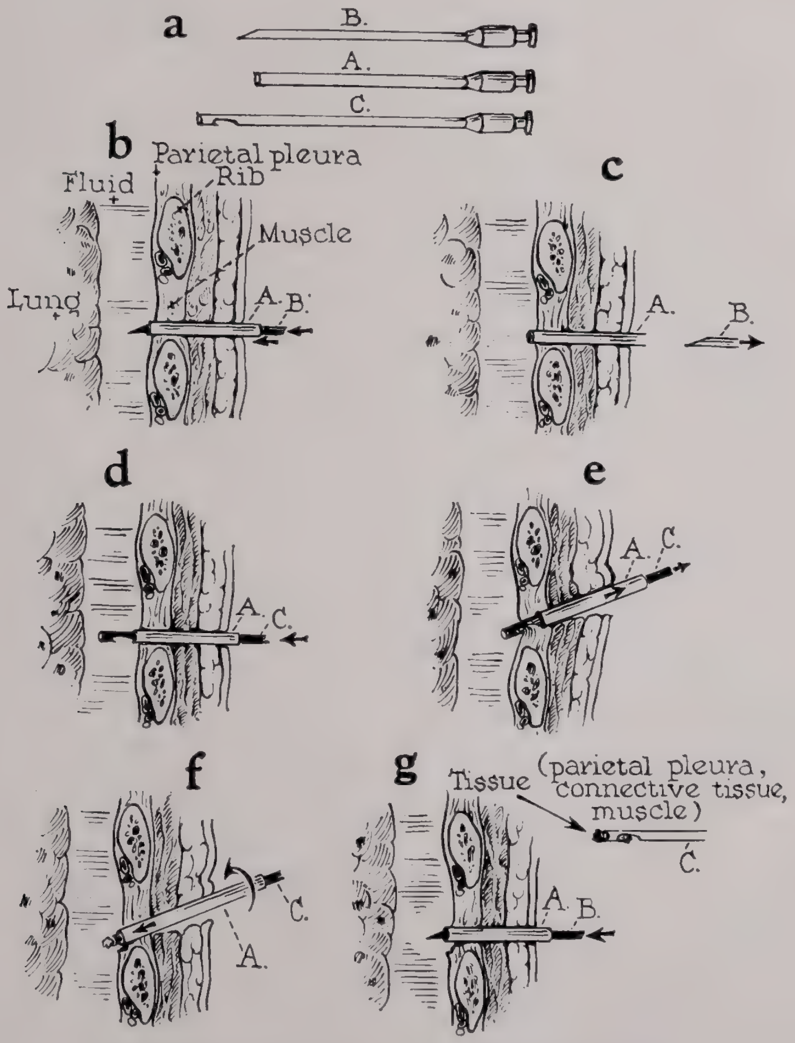
*See Grand Rounds: Needle of the Parietal Pleura, page 1011.

Preparation of the Site and Anesthesia

The usual preparation should be made, after which generous amounts of local anesthetic should be introduced. It is very important that complete anesthesia of the pleura be obtained. The cooperation of the patient in breath holding is required during the biopsy; a patient in pain is not likely to be cooperative. It is often recommended that the patient hold his breath when the infiltration needle is in the pleural space.

Withdrawal of Fluid

The outer cannula of the Cope needle is an excellent thoracentesis needle. Usually it is advisable to draw off sufficient fluid for all diagnostic tests prior to the performance of the biopsy, thereby avoiding the adulteration of the specimen by any bleeding which may be caused by the biopsy. If a very minimal amount of



Figure*—Components of Cope needle and method of use.

*L. J. Kettel and D. W. Cugell's: Pleural Biopsy. JAMA 200:4:317, April 24, 1967 by permission of authors and JAMA.

fluid is present it may be advisable to do the biopsy initially.

Technique

The Cope needle is shown in Figure 1. The technique below is that described by Cope. The biopsy entails little morbidity and, since it is essentially a sampling procedure, at least three bites should be taken at each biopsy site. In fact, there is no contraindication to using two or three different biopsy sites at a single sitting. Pleural tissue is recognizable as white, yellowish-white, or gray-colored tissue attached to the red muscle invariably removed at biopsy. A biopsy attempt should not be concluded until such tissue is secured.

Using the Needle

Following local anesthesia and after the presence of fluid has been ascertained with a fine exploratory needle, the skin is nicked with a scalpel blade (No. 11); the 13-gauge needle, which is inserted within the cannula, is then slowly advanced with a twisting motion until fluid is aspirated in the connecting syringe; next, the inner needle is removed and the blunt-tipped hooked biopsy trochar, attached to a three-way stopcock, is quickly substituted within the cannula. If the cannula opening is covered by the left thumb between substitutions and the patient instructed to hold his breath and bear down during the needle exchange, little or no air will enter the chest. Sufficient fluid for diagnostic purposes is aspirated through the three-way stopcock. Both the cannula and the biopsy trochar are then slowly withdrawn *together*, while lateral pressure is applied in the direction of the hook, until the instrument is *felt* to catch the parietal wall; the right hand keeps a light but *steady traction* on the biopsy trochar while the left hand advances the outer cutting cannula with a rotating motion until the biopsy specimen, anchored within the hook, is sliced off and the instrument can be withdrawn.

The biopsy procedure is then repeated through the same skin incision with the hook biting in the opposite direction. Since needle biopsy is a sampling procedure, a total of three to five bites should be taken at two or more different sites at the same sitting, especially if the initial samples appear normal on gross examination. One or two pieces of tissue should be submitted for culture for tuberculosis and fungi. The pleural cavity is not completely drained of fluid until just before the last biopsy specimen is obtained. Once the correct technic is mastered, pleural tissue can be obtained with every bite.

Post-Biopsy Orders

Vital signs should be monitored at one-hour intervals for six hours. A post-biopsy chest film should be obtained within a few hours to detect hemothorax or pneumothorax.

Minnesota Medicine at a Glance

Thioflavine-T—*Peterson and Gorlin* Page 899

Basal cell carcinoma and ameloblastoma show similarities in staining qualities, a tendency to be locally invasive and to recur if not adequately removed. The thioflavine-T positivity may be an amyloid-like mucopolysaccaride or a mucoprotein.

Corrosive Esophagitis—*Johnsen and Duvall* Page 909

Esophageal stricture, due to ingestion of corrosive substances, continues to be a common clinical problem. This occurs most commonly in mentally deficient individuals or in pediatric patients with neglectful parents. Additional cases arise following suicide attempts. The early use of antibiotics and steroids appears to reduce the inflammatory response and to prevent or minimize late stricture formation. Dilatation is often the treatment of choice. Surgery is sometimes necessary.

Tumors of the Upper Lip—*Abu Jamra et al.* Page 915

A statistical review of tumors of the upper lip treated at the Mayo Clinic from 1944 to 1963.

Placental Localization—*Meyer and Malkasian* Page 1001

The various techniques currently employed in placental localization are thoroughly discussed along with their respective advantages and disadvantages. These include localization by soft tissue x-ray, amniography, arteriography, intravenous placentography, isotopic placentography, thermography and ultrasound. The authors stress the fact that all of these give a high degree of accuracy (better than 90%) and that the selection of one over another depends upon available personnel and facilities.

Subinguinal Varix—*Lofgren* Page 1021

A subinguinal varix is caused by a swelling of the most proximal portion of the greater saphenous vein and is easily confused with a femoral hernia. While a hernia may not be reducible, a subinguinal varix will always disappear with finger pressure. The most reliable diagnostic sign is the transmission of a venous pulse either from the varix downward into the saphenous vein or from the saphenous vein into the varix. Associated varicose veins of the leg are commonly seen with this disorder. The treatment is surgical. The findings in eight women and two men with subinguinal varices are reviewed.

Blue Shield wants to know you by number, as well as your name!

Payments on claims are now processed by doctor's code number, rather than name.

A missing or incorrect code number will cause confusion and delay . . . In certain cases, the payment may even be sent to the wrong person.

BLUE SHIELD
OF MINNESOTA

Whenever anxiety induces or intensifies clinical symptoms

Librium®

(chlordiazepoxide HCl)

Quickly relieves anxiety ~ Helps improve response in psychophysiologic disorders ~ Seldom impairs mental acuity or physical coordination, on proper dosage ~ Has wide margin of safety

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Indicated when anxiety, tension and apprehension are significant components of the clinical profile.

Contraindications: Patients with known hypersensitivity to the drug.

Warnings: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reported on recommended doses, use caution in administering to addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potential benefits be weighed against its possible hazards.

Precautions: In the elderly and debilitated, and in children over six, limit to smallest effective dosage (initially 10 mg or less per day) to preclude ataxia or oversedation, increasing gradually as needed and tolerated. Not recommended in children under six. Though generally not recommended, if combination therapy with other psychotropics seems indicated, carefully consider individual pharmacologic effects, particularly in use of potentiating drugs such as MAO inhibitors and phenothiazines. Observe usual precautions in presence of impaired renal or hepatic function. Paradoxical reactions (*e.g.*, excitement, stimulation and acute rage) have been reported in psychiatric patients and hyperactive aggressive children. Employ usual precautions in treatment of anxiety states with evidence of impending depression; suicidal tendencies may be present and protective measures necessary. Variable effects on blood coagulation have been reported very rarely in patients receiving the drug and oral anticoagulants; causal relationship has not been established clinically.

Adverse Reactions: Drowsiness, ataxia and confusion may occur, especially in the elderly and debilitated. These are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally, making periodic blood counts and liver function tests advisable during protracted therapy.

Usual Daily Dosage: Individualize for maximum beneficial effects. *Oral*—Adults: Mild and moderate anxiety and tension, 5 or 10 mg t.i.d. or q.i.d.; severe states, 20 or 25 mg t.i.d. or q.i.d. Geriatric patients: 5 mg b.i.d. to q.i.d. (See Precautions.)

Supplied: Librium® (chlordiazepoxide HCl) Capsules, 5 mg, 10 mg and 25 mg—bottles of 50. Libritabs™ (chlordiazepoxide) Tablets, 5 mg, 10 mg and 25 mg—bottles of 100. With respect to clinical activity, capsules and tablets are indistinguishable.

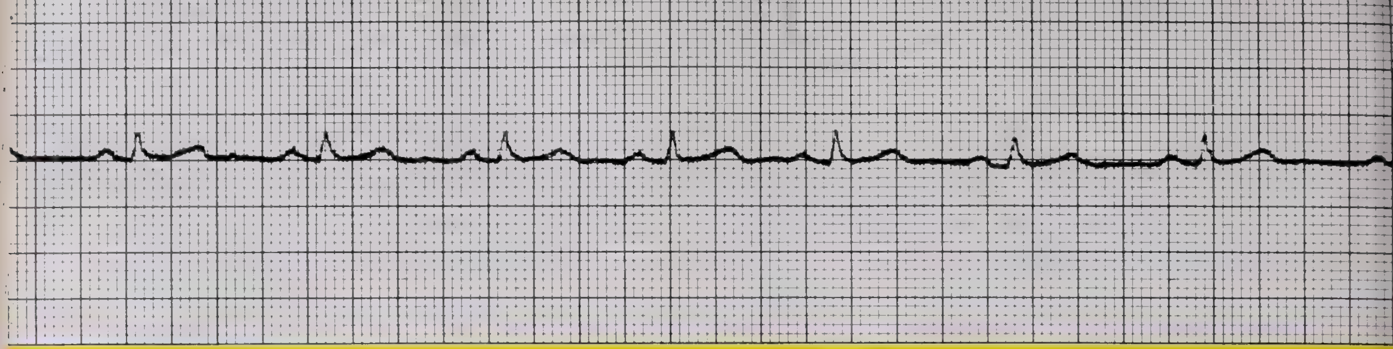
BLUE SHIELD
OF MINNESOTA



When disease is ruled out and psychic tension is implicated

Valium® (diazepam)

helps relax the patient and relieve his somatic symptoms

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Tension and anxiety states; somatic complaints which are concomitants of emotional factors; psychoneurotic states manifested by tension, anxiety, apprehension, fatigue, depressive symptoms or agitation; acute agitation, tremor, delirium tremens and hallucinosis due to acute alcohol withdrawal; adjunctively in skeletal muscle spasm due to reflex spasm to local pathology, spasticity caused by upper motor neuron disorders, athetosis, stiff-man syndrome, convulsive disorders (not for sole therapy).

Contraindicated: Known hypersensitivity to the drug. Children under 6 months of age. Acute narrow angle glaucoma.

Warnings: Not of value in psychotic patients. Caution against hazardous occupations requiring complete mental alertness. When used adjunctively in convulsive disorders, possibility of increase in frequency and/or severity of grand mal seizures may require increased dosage of standard anticonvulsant medication; abrupt withdrawal may be associated with temporary increase in frequency and/or severity of seizures. Advise against simultaneous ingestion of alcohol and other CNS depressants. Withdrawal symptoms have occurred following abrupt discontinuance. Keep addiction-prone individuals under careful surveillance because of their predisposition to habituation and dependence. In pregnancy, lactation or women of childbearing age, weigh potential benefit against possible hazard.

Precautions: If combined with other psychotropics or anticonvulsants, consider carefully pharmacology of agents employed. Usual precautions indicated in patients severely depressed, or with latent depression, or with suicidal tendencies. Observe usual precautions in impaired renal or hepatic function. Limit dosage to smallest effective amount in elderly and debilitated to preclude ataxia or oversedation.

Side Effects: Drowsiness, confusion, diplopia, hypotension, changes in libido, nausea, fatigue, depression, dysarthria, jaundice, skin rash, ataxia, constipation, headache, incontinence, changes in salivation, slurred speech, tremor, vertigo, urinary retention, blurred vision. Paradoxical reactions such as acute hyperexcited states, anxiety, hallucinations, increased muscle spasticity, insomnia, rage, sleep disturbances, stimulation, have been reported; should these occur, discontinue drug. Isolated reports of neutropenia, jaundice; periodic blood counts and liver function tests advisable during long-term therapy.

n Paintbrush

Thomas J. Kinsella, M.D.

JULY, 1969

Dear Doctor,
You made me
what I am today-
a whole lot
slimmer!

TEPANIL—the right start in support of the weight-control program *you* recommend. It reduces the appetite. Doesn't kill it. Weight loss is significant—gradual—yet there is a relatively low incidence of CNS stimulation. Because TEPANIL works on the appetite, not on the "nerves."

Contraindications: Concurrently with MAO inhibitors, in patients hypersensitive to this drug; in emotionally unstable patients susceptible to drug abuse.

Warning: Although generally safer than the amphetamines, use with great caution in patients with severe hypertension or severe cardiovascular disease. Do not use during first trimester of pregnancy unless potential benefits outweigh potential risks.

Adverse Reactions: Rarely severe enough to require discontinuation of therapy, unpleasant symptoms with diethylpropion hydrochloride have been reported to occur in relatively low incidence.

As is characteristic of sympathomimetic agents, it may occasionally cause *CNS effects* such as insomnia, nervousness, dizziness, anxiety, and jitteriness. In contrast, CNS depression has been reported. In a few epileptics an increase in convulsive episodes has been reported.

Sympathomimetic *cardiovascular effects* reported include ones such as tachycardia, precordial pain, arrhythmia, palpitation, and increased blood pressure. One published report described T-wave changes in the ECG of a healthy young male after ingestion of diethylpropion hydrochloride; this was an isolated experience, which has not been reported by others.

Allergic phenomena reported include such conditions as rash, urticaria, ecchymosis, and erythema.

Gastrointestinal effects such as diarrhea, constipation, nausea, vomiting, and abdominal discomfort have been reported.

Specific reports on the hematopoietic system include two each of bone marrow depression, agranulocytosis, and leukopenia.

A variety of miscellaneous adverse reactions have been reported by physicians. These include complaints such as dry mouth, headache, dyspnea, menstrual upset, hair loss, muscle pain, decreased libido, dysuria, and polyuria.

Convenience of two dosage forms: TEPANIL Ten-tab tablets: One 75 mg. tablet daily, swallowed whole, in midmorning (10 a.m.); TEPANIL: One 25 mg. tablet three times daily, one hour before meals. If desired, an additional tablet may be given in midevening to overcome night hunger. Use in children under 12 years of age is not recommended.

Tepanil® Ten-tab®
(continuous release form)
(diethylpropion hydrochloride)

THE NATIONAL DRUG COMPANY

PHILADELPHIA, PENNSYLVANIA 19144 T-818A U.S. PATENT NO. 3,001,910 5/69

LACTINEX®

TABLETS & GRANULES

■ to help restore and stabilize the intestinal flora

■ for fever blisters and canker sores of herpetic origin

Lactinex contains both *Lactobacillus acidophilus* and *L. bulgaricus* in a standardized viable culture, with the naturally occurring metabolic products produced by these organisms.

Lactinex has been shown to be useful in the treatment of gastrointestinal disturbances, and for relieving the painful oral lesions of fever blisters and canker sores of herpetic origin.[1,2,3,4,5,6,7,8]

No untoward side effects have been reported to date.

Literature on indications and dosage available on request.

HYNSON, WESTCOTT & DUNNING, INC.

He is a diabetic.
He is middle-aged.
When he needs an antibiotic
he may be a candidate for

DECLOSTATIN® 300 b.i.d.

Demethylchlortetracycline HCl 300 mg
and Nystatin 500.000 units
CAPSULE-SHAPED TABLETS Lederle

To guard susceptible patients against intestinal monilial overgrowth during broad-spectrum therapy—the protection of nystatin is combined with demethylchlortetracycline in DECLOSTATIN.

For your susceptible candidates, prescribe DECLOSTATIN—the broad-spectrum therapy that prevents monilial overgrowth.

Effectiveness: Because its antibacterial component is DECLOMYCIN Demethylchlortetracycline, DECLOSTATIN should be equally or more effective therapeutically than other tetracyclines in infections caused by tetracycline-sensitive organisms. The antifungal component, Nystatin, protects against superinfection by antibiotic-resistant fungal overgrowth (particularly monilia) in the intestinal tract.

Contraindication: History of hypersensitivity to demethylchlortetracycline or nystatin.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropriat measures should be taken. In infants, increased intracranial pressur with bulging fontanels has been observed. All signs and symptoms hav disappeared rapidly upon cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopapular and erythematous rashes; a rare case of exfoliative dermatitis ha been reported. Photosensitivity; onycholysis and discoloration of th nails (rare). Kidney—rise in BUN, apparently dose related. Transien increase in urinary output, sometimes accompanied by thirst (rare) Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxis Teeth—dental staining (yellow-brown) in children of mothers given thi drug during the latter half of pregnancy, and in children given the dru during the neonatal period, infancy and early childhood. Enamel hypoplasia has been seen in a few children. If adverse reaction or idiosy crasy occurs, discontinue medication and institute appropriate therap Demethylchlortetracycline may form a stable calcium complex in an bone-forming tissue with no serious harmful effects reported thus fa in humans.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should b given 1 hour before or 2 hours after meals, since absorption is impaire by the concomitant administration of high calcium content drugs, food and some dairy products. Treatment of streptococcal infections should continue for 10 days, even though symptoms have subsided.

GENERAL INFORMATION

Authors

Send manuscripts, subscriptions and communications for consideration to MINNESOTA MEDICINE, 375 Jackson Street, St. Paul, Minnesota 55101. Telephone 222-6366.

Illustrations, photographs, tables, graphs, and pen and ink drawings are encouraged.

All manuscripts will be edited and stylized to conform to the format used in MINNESOTA MEDICINE.

Minnesota Medicine Award

An award will be given at the annual meeting to the author of the most meritorious manuscript for the preceding year.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

Advertisers and Subscribers

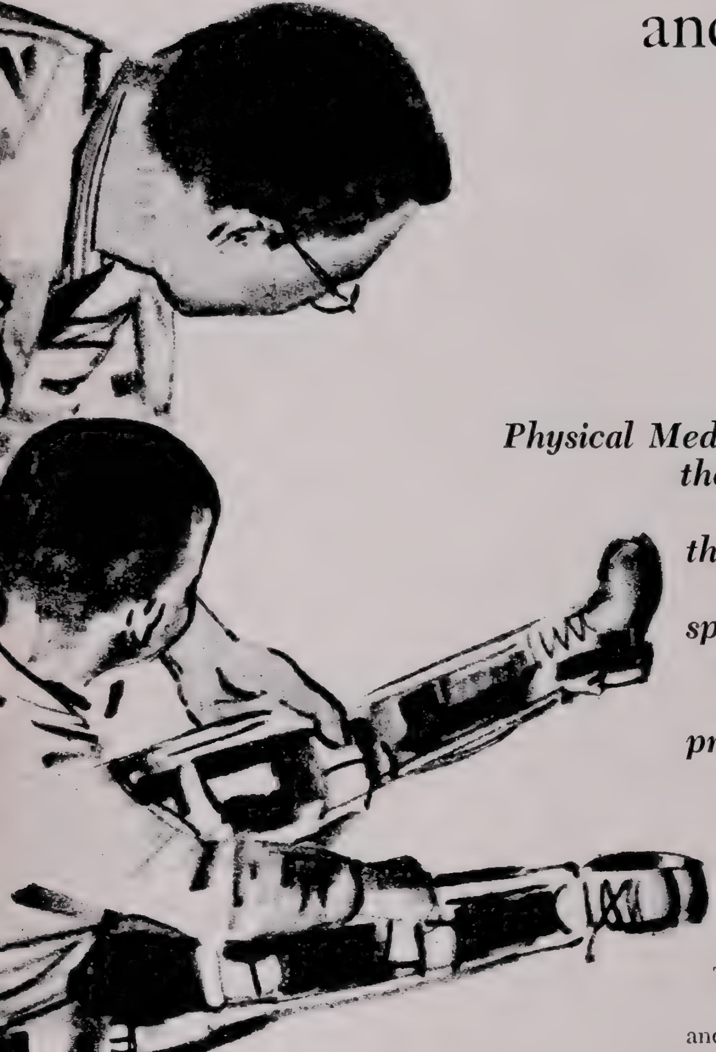
Fellowships

in PHYSICAL MEDICINE and REHABILITATION

UNIVERSITY OF MINNESOTA
SCHOOL OF MEDICINE
Minneapolis, Minnesota



Physical Medicine and Rehabilitation includes physical therapy, occupational therapy, rehabilitation counseling, guidance, and training of the physically handicapped, and is one of the most rapidly expanding and rewarding specialties in medicine. Trained physiatrists are insufficient in number and are in great demand in medical schools, private practice, Veterans Administration Hospitals, and many governmental institutions for the disabled. Physical Medicine offers unusual opportunities for the young physician seeking specialization.

The three-year residency program, beginning at any time, is approved by the American Board of Physical Medicine and Rehabilitation. The program may lead to a M.S. degree in physical medicine if desired. One year's credit in the residency is given for a year of training in another approved specialty or for four years of general practice experience. Ph.D. degrees are also offered for those planning a career in academic medicine. Extensive research facilities are available to interested residents and as part of programs leading to advanced degrees.

Salary is dependent on qualifications. Tax sheltered stipends are available in salary ranges from $6,000 to $11,000, plus $500 for each dependent. We will pay for visits in selected cases. Call or write for further information:

Chairman's Letter

Health Care Programs

IN RECENT YEARS doctors have been the object of much attention from the government and the communication media of the country. The "Winds of Change" have been blowing hard upon us, urging us to "new solutions" for the goal of medical care for all. The most recent exposure for pediatricians has been as consultants in the Head Start Program. In the fall of 1967 the American Academy of Pediatrics signed a contract with the OEO to provide consultants for this program, and over 600 pediatricians across the country have accepted such assignments.

The 38 projects in Minnesota are covered by 14 Minnesota pediatricians. Those of us involved have found ourselves studying methods for providing medical care to selected groups of children, as outsiders in the community to which we were assigned, and in such role we have now received much information from the National Head Start office about how medical care for children might be accomplished. No one approach has been insisted upon, however; the consultants have been free to advise whatever they think best, depending on the particular individual situation.

A. Frederick North, Jr., M.D., former Senior Pediatrician, Project Head Start, Office of Economic Opportunity, in a communication to Head Start consultants, has recently listed the problems in establishing a health care program for a group of children in a Head Start project as including the identification of "the preventive and restorative health needs of the children involved, identifying and mobilizing services and sources of funds to meet these needs, programming services that build on past health care and patterns for future health care for each child. . . .The planning must be done not for a single child, but for a group of children with diverse needs and patterns of care. Each child must be offered not a standard set of services, but an individual set of services that provides whatever he needs to insure his present and future health."

Additional "problems faced by anyone planning such a program include: what are the health problems to be found in a group of children? What techniques will efficiently identify the children who have each type of problem? What treatment or intervention technique will be most effective in remedying the problems? What financial resources and services are available in the community? How can they be used for Head Start Children? What administrative procedures will be necessary to assure that each child gets whatever services he needs? What can be done to make the future activities of the children and their families more effective in providing and maintaining good health?"

Can we program a computer to solve these problems? Listed in such a way the complexity of the task appears enormous. But there is something familiar about this dissection of Health Care. As the "Winds of Change" blow away the haze, we see revealed The Practice of Medicine! And what computer do we see emerging? Behold! A well-trained, conscientious physician!

We have come full circle.

ETHYLENE GLYCOL CAUSES an estimated 40 to 60 deaths a year in this country.[1,2] A major cause of death is the associated acute renal failure. The means for salvaging a significant number of these patients are available, if the process is recognized and treated early. The following case report demonstrates that a gratifying response may also be obtained relatively late in the course of the illness with the use of dialysis.

Case Report

History

A 59-year-old white male alcoholic was admitted to a local hospital on October 10, 1967, with a four-day history of anuria. At the time of admission, the patient was confused and markedly dyspneic. There was no history of previous neurological, renal, cardiac or pulmonary disease; nor had there been preceding fever, hematuria or abdominal pain.

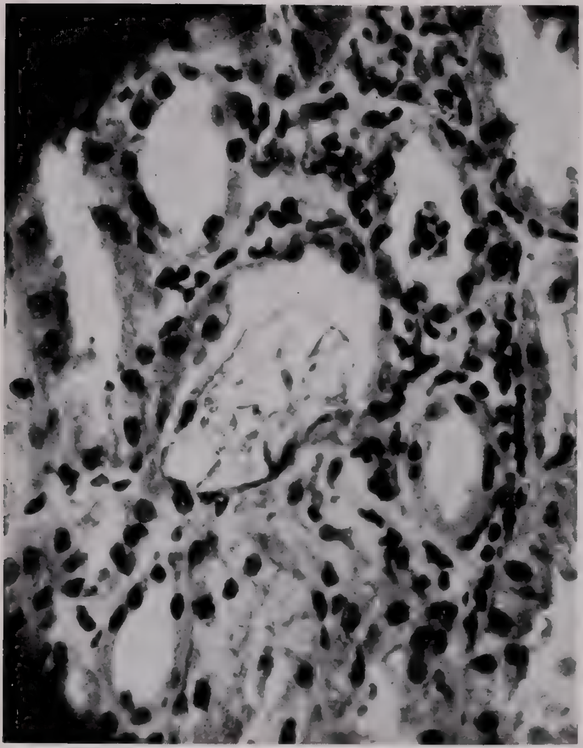

Fig. 2—Same crystal as in Figure 1 with polarized microscopy (×600)

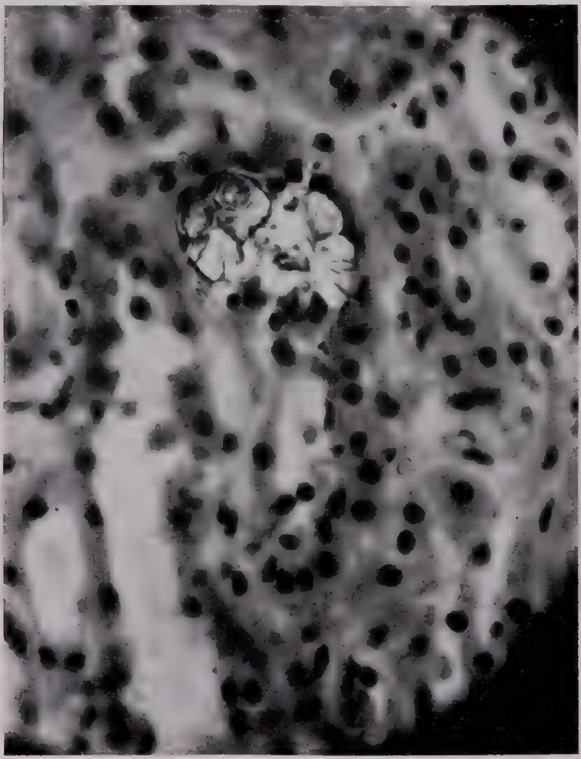

Fig. 3—Calcium oxalate crystal in renal biopsy with polarized microscopy (×600)

Laboratory Studies

Blood urea nitrogen was 81 mg %; serum potassium, 6.1 mEq/L; serum sodium, 124 mEq/L; serum chloride, 92 mEq/L; CO_2, 14 mEq/L; calcium, 9 mg %; creatinine, 15.6 mg %.

A chest x-ray demonstrated cardiomegaly and pulmonary edema.

Treatment and Progress

Peritoneal dialysis was begun immediately and produced gradual alleviation of the patient's respiratory distress. The following day a small amount of urine obtained for analysis revealed 4+ albuminuria; 3+ acetonuria; a specific gravity of 1.011; microscopic—a few bacteria and many red blood cells per high-power field. Cystoscopy and retrograde pyelography showed no evidence of obstruction.

Because the anuria persisted, a kidney biopsy was performed on October 26, 1967. The sections showed a coarse vacuolization in the epithelium of some of the proximal convoluted tubules. In addition, there were sheaves of crystals present in the tubular lumina and epithelium (Figures 1, 2 and 3). The interstitial tissue appeared slightly edematous and contained a few sparsely scattered leucocytes. The glomeruli, vasculature, basement membrane and Bowman's capsule appeared normal. The microscopic diagnosis was chemical nephrosis, probably ethylene glycol. Peritoneal dialysis was continued with four exchanges per day. On the sixth day the dialysate returns became purulent. Antibiotic therapy was initiated with the combination of chloramphenicol 250 mg intramuscularly every six hours, and kanamycin sulfate 250 mg intramuscularly every three days. Culture of the fluid grew out gram-negative rods of the Herella group, which were sensitive to kanamycin sulfate, but resistant to chloramphenicol.

Deterioration Followed by Recovery

Because of his rapid deterioration, manifested by lethargy, increased confusion, twitching and the development of pericarditis, the patient was transferred to the renal service at Hennepin County General Hospital. At the time of his admission there on November 8, 1967, he was delirious. His blood pressure was 150/90 mm of Hg, pulse rate 120/min and regular, rectal temperature 102.4°F. A loud precordial friction rub was present. There were fine inspiratory rales at both lung bases. The abdomen was distended and diffusely tender; there were no bowel sounds. The admission chest film revealed pulmonary edema. Laboratory data included serum potassium of 5.4 mEq/L, CO_2 28 mEq/L, blood urea nitrogen 81 mg %, SGOT 82 units, and creatinine 12.3 mg %.

Peritoneal dialysis was continued with exchanges on a 1½ hour cycle. There was a nine-pound weight loss over the succeeding 24 hours, but the confusion and cardiac friction rub persisted. Antibiotic therapy was changed to sodium cephalothin 1 gm intramuscularly every six hours and kanamycin 500 mg intramuscularly daily for six days. By November 13, 1967, the patient was afebrile and had normal bowel sounds. It was decided to discontinue peritoneal dialysis and use intermittent hemodialysis as needed. After the patient's mental status improved, he admitted that five days prior to the initial hospitalization, he had ingested approximately three ounces of an unlabeled liquid that he had discovered while painting a relative's home.

By November 15, 1967, the SGOT had increased to 190 units but then decreased (Figure 4). He was discharged from the hospital on December 2, 1967, 59 days post ingestion, and continued the intermittent hemodialysis on an out-patient basis. At the time of discharge, his urine output was 400 cc per day. It had increased to 3300 cc per day by December 20, 1967. He was discharged to the care of his private physician on December 26 with a blood urea nitrogen of 23 mg %, creatinine 1.7 mg %, potassium 5.3 mEq/L and serum glutamic oxaloacetic transaminase of 19 units.

One hemodialysis has been performed since the patient was discharged. He has continued in good health.

Discussion

Ethylene glycol ( $H{-}\underset{OH}{\overset{H}{C}}{-}\underset{OH}{\overset{H}{C}}{-}H$) is widely used as a solvent for dyes and drugs and as a constituent for antifreeze mixtures for automobile cooling systems. It is a nonvolatile, colorless, odorless liquid with a bittersweet taste.[3]

Toxicity

Bachem in 1917 and Page in 1927 drank, respectively, 45 cc and 15 cc of this compound without ill effects, thus emphasizing its nontoxicity.[2] Hunt,[4] however, in 1931, extrapolated from animal experiments that the human lethal dose was approximately 100 cc, an estimate generally borne out by subsequent reports of human fatalities. Fatal doses are quite variable, however, with death reported from ingestion of 60 cc while other patients have survived 240 cc.[3] After ingestion, some of the ethylene glycol is excreted unchanged in the urine in man and animals. Recent evidence suggests that only 3-10% of the amount ingested is converted to oxalic acid.[5,6] The intermediary steps in this process are noted in Figure 5.

Clinical Manifestation

The clinical events following ingestion are usually divided into three stages:[3] (1) central nervous system effects, (2) cardiopulmonary failure and (3) renal damage. Death may occur in any of these stages.

Central nervous system effects are usually noted 30 minutes to 12 hours after ingestion. With relatively small doses the signs may resemble those of ethanol* intoxication. The diag-

Who Follow A Gleam!

What was its etiology? Was it caused by cold, heat, diet, the moon; by contagion, miasmas (cosmic or telluric), lochial suppression, milk fever (milk pneumonia, milk peritonitis, milk meningitis), gastric biliousness, fibrin deposits culminating in crisis? Or was it intiated by depression, fear, shame, over-crowding, or maybe just rough treatment? This series by no means exhausted the preposterous but quite acceptable hypotheses for the etiology of puerperal fever when Ignaz Philip Semmelweis appeared on the mid-nineteenth medical horizon—to demolish once for all all cart-before-the-horse theories.

Semmelweis' lone and Olympian crusade is familiar to most students of medical history but no less unforgettable now than when Destiny charged him with it.

Voiding space and time we join him in Vienna at the Lying-in Hospital with its two pavilions: Klein's, where the medical students, direct from their autopsy assignments, attended the women patients in labor, and Bartsch's where midwives were trained. Appalling mortality rates prevailed in both pavilions, noticeably higher in Klein's, however, than in Bartsch's. In that puzzling discrepancy lay the key Semmelweis sought: the students, he reasoned, must be conveying something on their hands directly from cadaver to patient. What that something was was invisible, Semmelweis conceded; but since it was not odorless, it could be eliminated by having the students wash their hands until no odor was any longer perceptible.

"Wash hands!" his superiors exploded. "Ridiculous!" Whereupon Semmelweis flew into a rage: a most unseemly exhibition of temper among his smug, complacent colleagues.

"Assassins!" cried Semmelweis. . . . "It is not the maternity hospitals that should be closed to put a stop to the deplorable disasters of which they are the scene, but rather the obstetricians themselves should be driven out, for it is they who behave like real epidemics."

But Semmelweis convinced nobody. True, he had a few friends and supporters; yet when all was said and done, he walked alone, his triumph and vindication delayed until too late.

Had Semmelweis been more patient, more compromising, more diplomatic, the outcome might have been different. But the cooler virtues of patience, compromise, diplomacy do not come natural to revolutionaries; Semmelweis' arsenal contained only the savage fire of his titanic conviction.

A long sequence of scorn, revilement, hostility, ostracism, defeat and dismissal, with the insulting title of "Professor Unattached," shattered the immortal Magyar, culminating in violent and shuddering dementia. One day "he was seen rushing through the streets, pursued by the mob of his imaginary enemies. Howling, he burst into the anatomical amphitheater of the Medical Faculty. A cadaver lay there on the marble, stretched out ready for a demonstration in dissection. Semmelweis seized a scalpel, pushed himself through the circle of medical students, and thus came nearer to the slab. He punctured the skin of the cadaver, shoved the scalpel deep into the putrid tissues before anyone realized what he was doing. He cut the muscles away in strips, hurled them far behind him. . . . Now he took up the scalpel again and explored with his fingers and the blade together a cavity in the dead body which was oozing with liquefaction. With a gesture more abrupt than before, he cut himself profoundly. . . . The wound began to bleed. He shouted. He uttered menaces. He was disarmed at last. But it was too late. . . . As Kolletschka had done years before, he had infected himself fatally." Semmelweis wrote "The Etiology of Puerperal Fever": his grand masterpiece of inductive reasoning and investigation.

Vascular Compression of the Distal Duodenum

Clinical Symptoms*

S. K. IMES, M.D.†
Bismarck, North Dakota

VASCULAR COMPRESSION of the distal duodenum is not a new entity. In 1842 Rokitanski[1] first suggested the duodenum might be compressed by the superior mesenteric artery. This syndrome has been described under a number of synonyms, including the superior mesenteric artery syndrome, arteriomesenteric duodenal compression, chronic duodenal stasis, and Wilkie's syndrome.

Literature about this subject well documents the radiologic abnormalities but does not equally well correlate the symptoms with the radiographic findings. This is particularly true with regard to the duodenum in patients treated medically. This paper summarizes the findings in eleven cases of this syndrome and correlates the clinical status with the radiologic findings before and after therapy.

Anatomical Considerations

An excellent and complete resumé of the embryology and gross anatomy of the involved region may be found in the review article of Barner and Sherman.[2]

For the purposes of this paper we reiterate that the third portion of the duodenum lies normally trapped in a potential anatomic pincers‡ the anterior limb of which is formed by the root of the mesentery of the small bowel with its vascular elements. The posterior limb of the pincers is composed of the lumbar spine, the aorta, or the paravertebral muscles. Any mechanism that increases the obliquity of the mesenteric angle closes the pincers and results in compressive occlusion of the distal third of the duodenum.

Fat in the root of the mesentery acts to cushion the third portion of the duodenum from compression; consequently this phenomenon has never been observed in an obese person. Hence, weight loss predisposes to development of the syndrome. The more asthenic the patient, the less weight loss is necessary to produce symptoms.

---

* See editorial page 1079.

†The Department of Radiology, Quain and Ramstad Clinic, Bismarck, North Dakota.

‡See Test Your Word Score Page 1087.

Clinical Picture

Because of the widely varied factors capable of producing this anatomic defect, the age of onset of symptoms varies. In the newborn, congenital anomalies may be the precipitating factor. In the aged patient weight loss and forced bed rest in the supine position may acutely precipitate the syndrome, particularly if the lumbar lordosis is increased by hyperextension of the spine.

We are reporting eleven cases of this syndrome discovered in performing 1,643 upper gastrointestinal radiographic studies on outpatients at the Quain and Ramstad Clinic in a period of 14 months. The youngest of these eleven patients was six years of age and the oldest was twenty-six.

Obstructive Symptoms

The symptoms are due to duodenal distention and partial high small-bowel obstruction. Nausea and/or anorexia are present in nearly all cases. Emesis is also a frequent symptom.

Pain

Pain is a common complaint and is usually epigastric in location, often crampy, occurring soon after meals when semisolids are traversing the duodenum. Pain may occur at night if the supine body position has increased the pincers effect. Many patients will have discovered that curling up on one side or the other, sleeping on the stomach, or assuming the knee-chest position will afford relief, as these positions will open the anatomic pincers. Relief also occurs after vomiting.

The symptoms tend to be chronic, recurrent and episodic. Frequently there are symptom-free periods of days to weeks between attacks. Many patients relate a history of recent weight loss to a recurrence of symptoms. The symptom complex may simulate that of biliary tract disease, peptic ulcer, or pancreatitis. There is evidence that chronic duodenal obstruction probably predisposes to both peptic ulceration and pancreatitis.

X-Ray Findings

Radiologic examination of the upper gastrointestinal tract remains the one reliable method of diagnosis. The initial swallows of barium with the patient erect are likely to show a considerable amount of secretion in the stomach and possibly some gastric dilatation, but with no evidence of outlet gastric obstruction unless there is complicating disease at the pylorus or duodenal bulb. The duodenal bulb will probably be distended. Occasionally antiperistalsis is normally seen to a minimal degree as the first bolus of barium traverses the normal duodenum; but continued or exaggerated reverse peristalsis is not physiologic. In duodenal occlusion, this reverse peristaltic activity is marked and forceful and produces a writhing effect proximal to the obstruction.

Dilatation of the duodenum proximal to the occlusion is always present. Frequently, and especially in long-standing cases, forceful reverse peristalsis distends the duodenal cap and then regurgitates the duodenal contents into the stomach through a patulous* pylorus, the duodenum tending to remain more or less filled up to the point of occlusion. In contrast the normal duodenum is usually only partially filled with the contrast medium. Elongation and redundancy of the duodenum may be present. In the erect right anterior oblique or in the erect lateral fluoroscopic position, the vertical slit-like compression of the distal third portion of the duodenum between the anterior and posterior limbs of the pincers becomes visible.

Even with surging peristaltic activity, the symptomatic patient has no more than small jets of barium pass the level of the compression in the erect position. Barium in small amounts can be forced through the occlusion by increasing the intralumenal pressure proximal to the obstruction by the palpating hand. In the symptomatic patient, the occlusion is usually maintained in the supine position, but can be relieved to a considerable degree in either the left or the right lateral position, the right anterior supine position, or especially in the knee-chest position. For all practical purposes, no other etiology of distal duodenal obstruction will demonstrate this positional relief of the obstruction.

Therapy

Medical

A trial of medical therapy is indicated in nearly all cases. In fact, Bockus[3] has stated that he has never found it necessary to resort to surgical intervention. The success of medical therapy has, however, not been constant in the experience of most physicians. Medical therapy varies according to the severity and the acuteness of the symptoms. The acute episode may require suction tube decompression, intravenous feeding and positional treatment, followed by intermittent ambulation; small, frequent, liquid, high caloric feedings; post-prandial positioning; sleep positioning; and sleeping with the foot of the bed elevated. Antispasmodics and antacids probably have little to offer in the uncomplicated case.

---

*See Test Your Word Score Page 1087.

Peptic ulceration or other complications should receive appropriate individual therapy and may in themselves be indications for surgery. Exercises should be instituted to correct abdominal wall muscular deficiencies or lumbar hyperlordosis. Abdominal supports may be useful. Every effort should be made to encourage the underweight patient to gain weight, inasmuch as this factor alone will relieve the symptoms of many patients as a fat pad is added to the mesentery. Diet may be increased and positioning therapy relaxed as the patient gains weight and becomes asymptomatic. The less acute, the chronic and the recurrent patient may be adapted to this regimen at his appropriate level.

Surgery

As early as 1920 Quain[4] reported on the surgical treatment of this abnormality. Surgery should be reserved for those cases where adequate medical therapy fails to relieve the patient's symptoms and produce adequate weight gain and possibly for those cases with complicating ulcer disease or pancreatitis. Barner and Sherman quoted results of surgical therapy as: good, 77%; fair, 13%; poor, 3%; unknown, 2%, and deaths, 4%. Their medical therapeutic statistics list results as good in 50%, fair in 25%, poor in 10%, unknown in 15%. (These figures were corrected for mathematical accuracy.) A valid comparable study of surgical and medical therapeutic results on similar patients is not available.

Case Report Summaries

Table 1 lists the summary of the clinical data related to these eleven patients.

It is noted that clinically all patients presented with cramping, epigastric pain, and nausea. Nine of the eleven patients reported vomiting; eight complained of anorexia. All eleven patients were either quite asthenic in stature or had recently lost significant body weight.

Table 2 summarizes the radiologic findings in these eleven patients.

The radiologic diagnostic abnormalities (gastric retention, proximal duodenal dilatation, duodenal regurgitation, significant reverse duodenal peristalsis and positional relief of the distal duodenal obstruction) were found in all eleven patients.

Follow-up Studies

The status of these eleven patients following therapy is listed in Table 3.

Excellent correlation is demonstrated between the degree of weight gain, the relief of symptoms, and the radiologic demonstration of relief of distal duodenal obstruction.

Case Reports

Four cases were of special interest because of certain facets of their histories, findings, and delayed studies.

Case 1

A 21-year-old lady who had intentionally lost eight

pounds to more nearly attain a "Twiggy-look." She learned to control her episodic symptoms with diet, after-meal positioning and sleep positioning when symptoms occurred, and had no intention of adding weight.

Case 8

A lady who had lost 30 pounds and had moderately severe symptoms with radiologic findings of distal duodenal obstruction. Through lack of communication between the Radiology Department and the clinician, this lady received no treatment. At the end of six months her symptoms and radiographic findings were identical with those at the initial study. She was then placed on a moderately strict medical regimen; and, three months later with a weight gain of 18 pounds, she was asymptomatic and an upper gastrointestinal radiologic study was normal.

Case 11

A 26-year-old lady who had been considerably overweight since childhood. By dieting she gradually reduced her weight from approximately 180 to 130 pounds and at this weight level presented with abdominal discomfort of recurrent and indefinite nature. An upper gastrointestinal radiologic study at that time appeared normal. During the next nine months she unintentionally reduced to 116 pounds; at this weight she returned with characteristic symptoms of vascular duodenal compression. A re-check upper gastrointestinal series demonstrated class and marked findings of vascular compression of the distal duodenum. She was placed on a medical regimen with frequent high caloric feedings and post-prandial positioning. Within one month she had regained ten pounds, was symptom-free, and has remained so at this weight for a period of twelve months.

Case 7

Of considerable interest was the one complete failure of medical therapy: a young man who has always been asthenic in stature. He was 5 feet, 11 inches tall and weighed 116 pounds. For as long as he could remember he had always had recurrent crampy post-prandial upper abdominal pain, with severe disabling episodes associated with vomiting lasting for periods of up to a week. Three years before our first radiographic examination he was thought to have had a superficial duodenal ulcer on gastrointestinal x-ray studies done elsewhere. Vagotomy and pyloroplasty were performed at that time, and he was discharged with an associated clinical diagnosis of pancreatitis based on a transient elevation of serum amylase during hospitalization. Despite this, his symptoms remained unchanged.

Our upper gastrointestinal series three years later demonstrated severe vascular duodenal compression of the distal duodenum; and review of the original radiographs revealed that the earlier obstruction had been equally severe. The patient was hospitalized and placed on a rigid medical regimen with only temporary and partial relief of symptoms. Within a month, in spite of careful adherence to the medical regimen, he had to be re-hospitalized, and a gastrojejunostomy was done. Postoperatively he has remained free of duodenal obstructive symptoms for a period of well over twelve months; but unfortunately he has had recurrent episodes of pancreatitis with increasing frequency and severity in spite of careful medical management. Recently he has had a duodenojejunostomy performed to provide better drainage of the duodenal loop inasmuch as his re-check upper gastrointestinal x-rays have repeatedly demonstrated considerable stasis in the duodenal loop and continued regurgitation of duodenal contents into the stomach. At the recent surgery, the common bile duct was explored and found to be stenotic at its distal end. A sphincterotomy was then done. Significant time has not elapsed, however, to evaluate the clinical effects of the latest procedures on the pancreatitis.

Summary

Vascular compressive disease of the distal duodenum can produce nausea, vomiting and pain—typical symptoms of duodenal obstruction. X-ray studies confirm the diagnosis. Asthenic body stature and recent weight loss are felt to have been most important to the development of symptomatology in all of these cases. Radiologic studies at the time of diagnosis and repeat studies on eight cases following therapy demonstrate close correlation of clinical symptomatology and radiologic findings.

Old Hospitals

Hospital de Jesús Nazareno, Mexico City.

Oldest Hospital in the Americas.

Pictured is a courtyard of the Hospital de Jesús Nazareno in Mexico City. Founded in 1523 by Hernando Cortés, the conqueror of Mexico, it is the oldest hospital in the western hemisphere. In a conference room, frequently used by Cortés himself, hangs the only portrait of the founder ever done in life. Cortés' remains are in the church connected to the hospital.

The original building is still in use, housing the surgical suite, administration and business offices, and the kitchen. In 1942, the old building was surrounded by a modern hospital and medical office building. It is located about three blocks south of the Zócalo or main square of the city, within easy reach of visitors. The hospital has developed its own plan to provide hospitalization for persons not covered by Mexican Social Security.

Everything that exceeds the bounds of moderation, has an unstable foundation.—Seneca

Congenital Pseudarthrosis of the Ulna

Report of Two Cases

JOHN H. SHERTZER, M.D.*
WILLIAM H. BICKEL, M.D.†
Rochester, Minnesota
SAM G. STUBBINS, M.D.‡
Cleveland, Ohio

CONGENITAL PSEUDARTHROSIS of long bones in children is uncommon, although, when present, it most frequently involves the tibia. There are rare reported cases of this congenital anomaly affecting other long bones, including the fibula, femur, clavicle, humerus, first rib, and ulna. A review of the English literature reveals two cases of congenital pseudarthrosis of the ulna.[1-3] The two patients whose cases are presented in this paper were treated by several orthopedists and their treatment represents different approaches to the management of this uncommon problem.

The therapeutic objectives of treating congenital pseudarthrosis of the ulna are primarily to maintain good function of the hand and secondarily to prevent or decrease deformity and maintain length of the forearm.

In the first case, the distal ulna was excised and the distal radius osteotomized. In the second case, three bone-grafting procedures were required to effect union of the ulna and maintain functional alignment of the hand on the forearm. Both patients have had sufficiently long follow-up periods to allow final appraisal of the therapeutic program employed.

Report of Cases

Case 1

This five-year-old boy was first seen in September 1956. The chief complaint was mild lateral bowing of the left forearm. There was no history of trauma, pain, or disability related to the deformity. At the original orthopedic examination, the patient was noted to have many café-au-lait§ spots widely distributed on his trunk. Roentgenographic examinations of the left forearm when the patient was one year old, three years old, and five years old (1956) revealed congenital pseudarthrosis of the left ulna (Figure 1 A). Since there was minimal disability it was elected to observe the child for increasing disability or deformity. The boy was examined periodically, and in 1961 the lateral bowing of the left forearm was noted to have increased significantly (Figure 1 B).

First Operation

In July 1961, when he was 10 years old, the distal ulna consisting "mostly of white fibrocartilage" was excised and a wedge of the distal radius removed, thus placing the hand in a better functional position. The osteotomy site appeared to heal satisfactorily, but one year later the boy injured his left forearm and a roentgenographic examination revealed a fracture through the osteotomy site.

§See Test Your Word Score Page 1087.

Second Operation

In June 1962, a second operation consisting of bone grafting across the fracture site was done, using iliac bone and Kirschner-wire fixation. This procedure produced a solid union (Figure 1 C), and in six months the patient was permitted to engage in normal activities, with the exception of body-contact sports.

The boy was seen most recently in September 1967, when he was 16 years old, seven years after the distal portion of the ulna had been excised. Clinically, there was minimal bowing deformity, but obvious shortening of the left forearm was present (Figure 1 D). Hand function was good, although forearm motion was impaired.

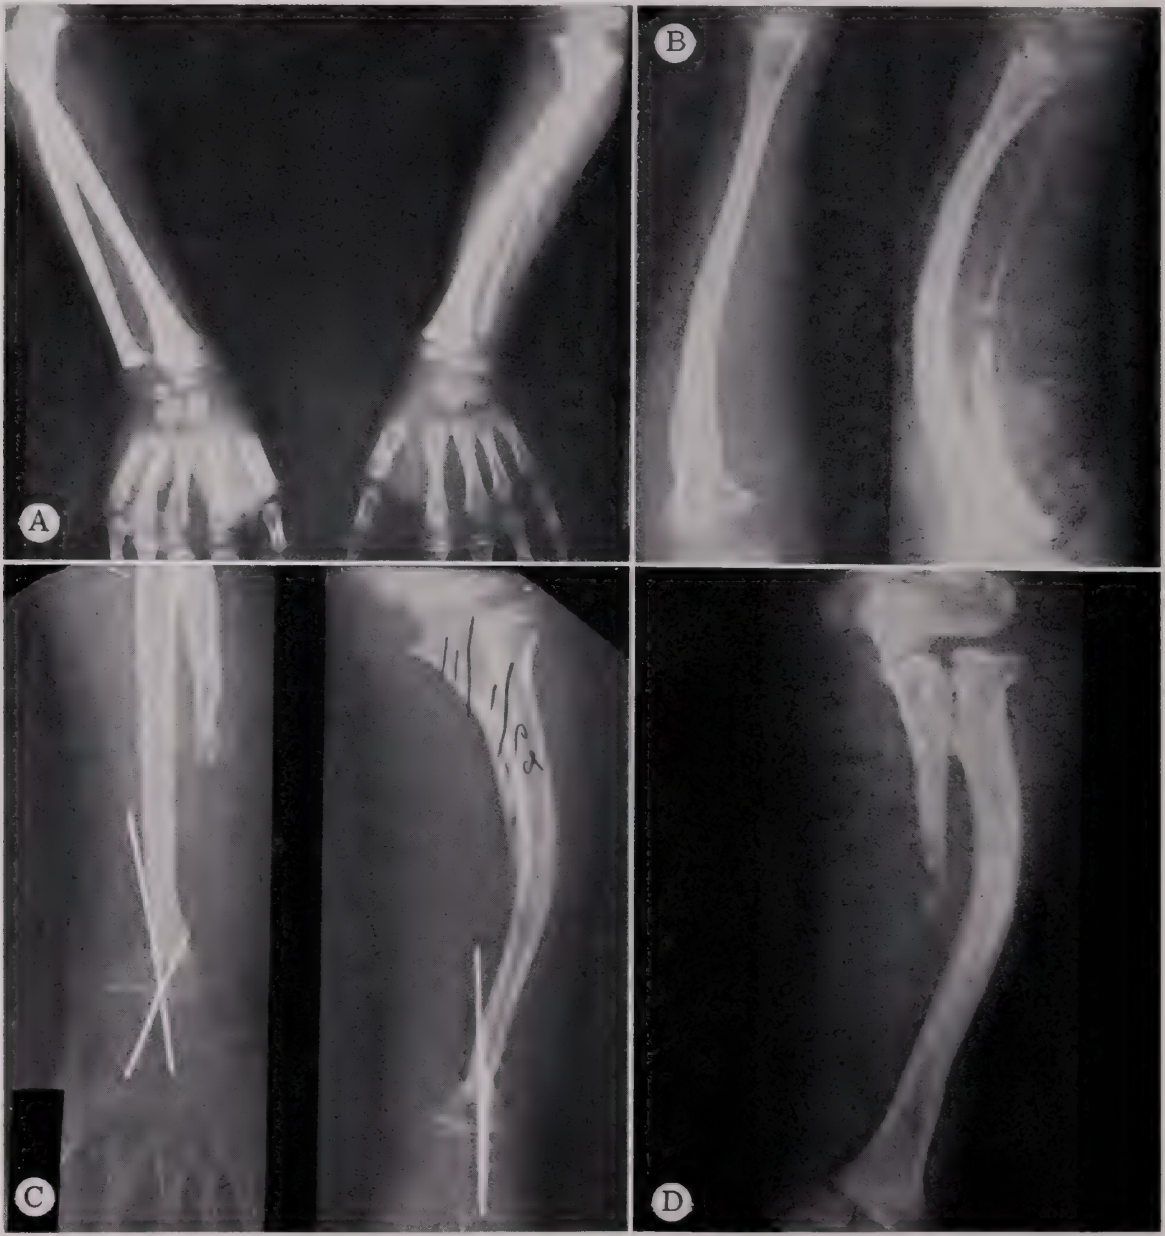

Fig. 1—(Case 1). (A), Patient at five years (1956). Both forearms showing congenital pseudarthrosis of left ulna, with mild shortening and lateral bowing of left radius. (B), July 1961. Bowing of left radius has increased significantly, and the thin atrophic ulna appears to be producing a bowstring effect. (C), November 1962. Five months after second operative procedure on left forearm. Distal radial osteotomy appears united. (D), Patient at 16 years (1967). Left forearm six years after resection of distal ulna for congenital pseudarthrosis. Lateral bowing of radius has persisted and increased slightly.

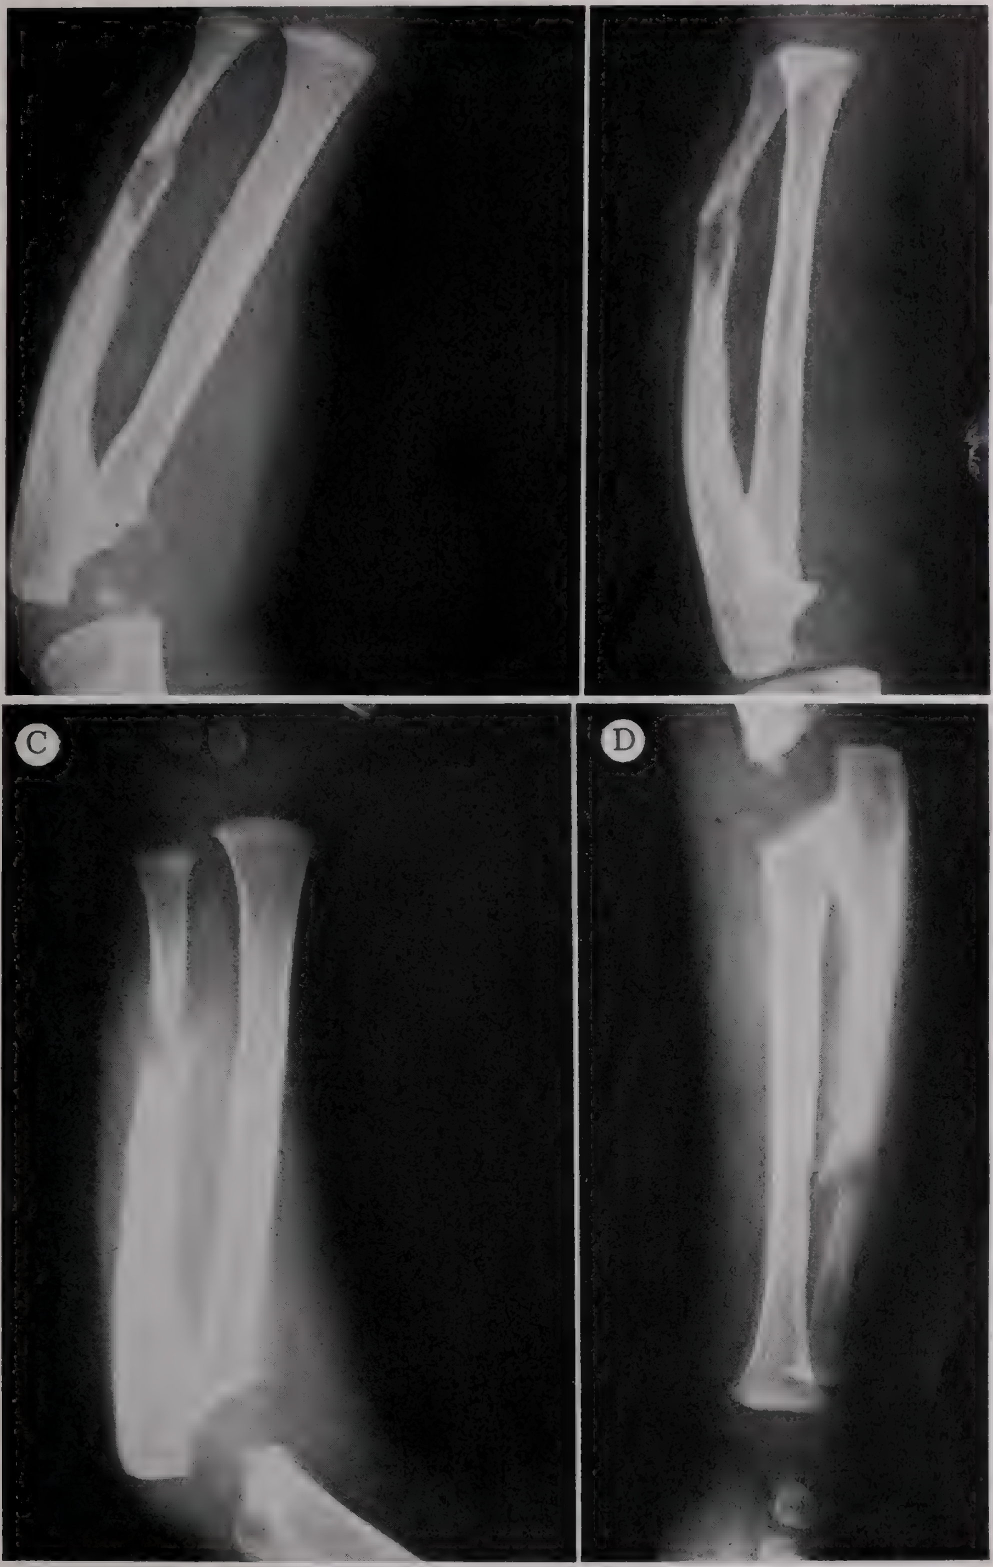

Fig. 2—(Case 2). (A) and (B) (top) Patient at 13 months (January 1955). Left forearm shows cystic lesion in ulna. There is also an irregularity of proximal ulnar cortex and an abnormal conformation of left radius. (C) and (D), May 1955. Left forearm after four months of long arm cast immobilization. Obvious pseudarthrosis with mild shortening of ulna and mild bowing of radius. Apparent periosteal reaction of radius and ulna is an artifact owing to motion when roentgenogram was taken.

Case 2

This patient was seen when she was 13 months old in January 1955 because her mother had noticed swelling on the proximal end of the ulnar side of the left forearm. The child had no noticeable discomfort when she used her left upper extremity, which she did normally. There was no history of trauma to the child or a similar deformity in the family. The child had 20 to 30 brown pigmented lesions on her face and trunk, which were present at birth and were described as café-au-lait spots. Roentgenograms of the left forearm showed a "cyst in the left ulna, with a pathologic fracture" (Figures 2 A and B).

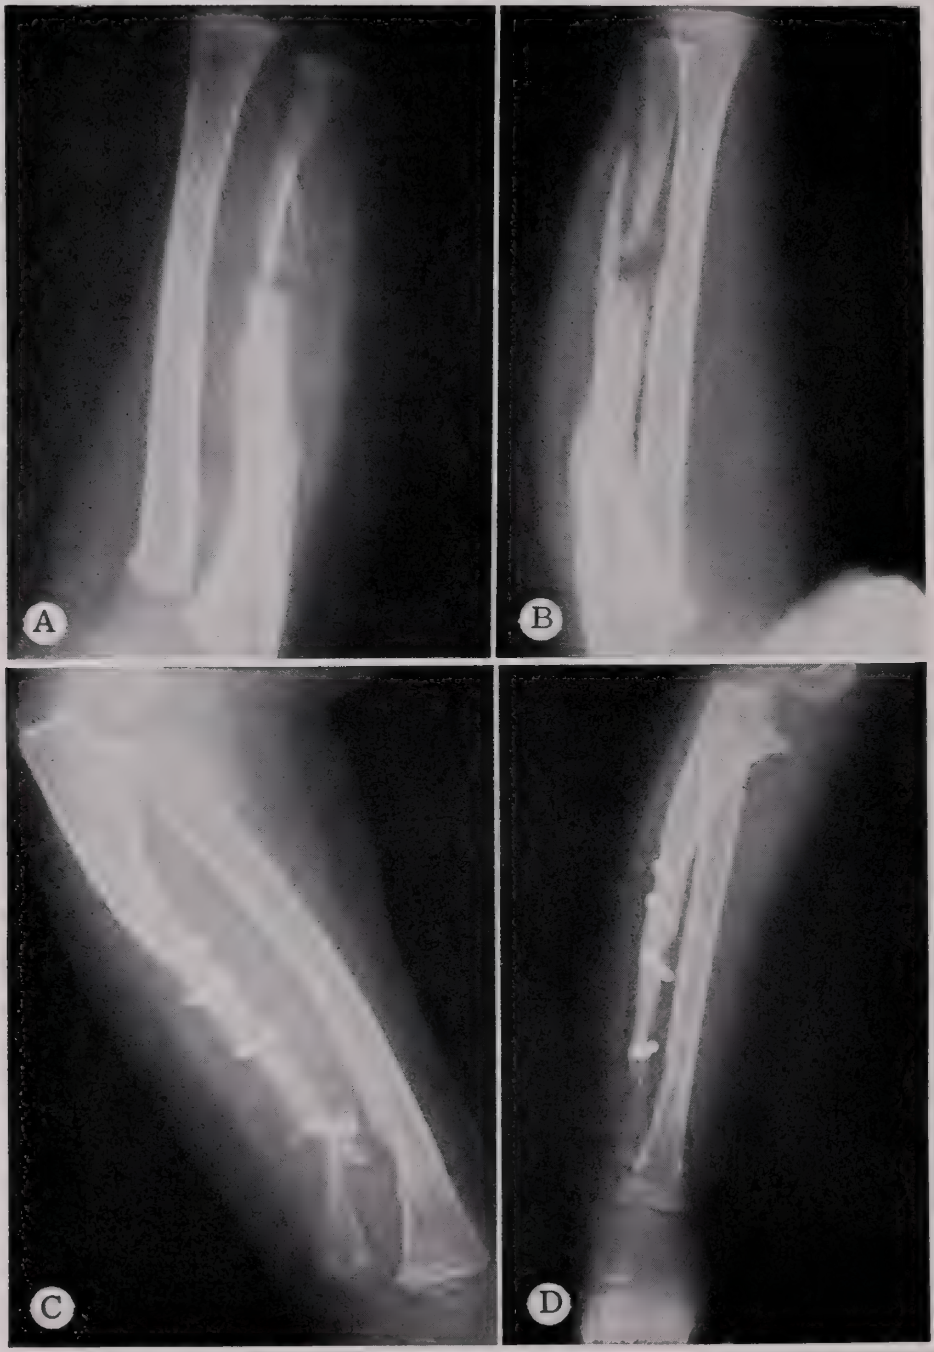

Fig. 3—(Case 2). (A) and (B), July 1955. Tibial bone graft to left ulna six months after operation. Graft failed to unite to either the proximal or distal ulna. (C) and (D), April 1957. Four months after second tibial bone grafting procedure for congenital pseudarthrosis of ulna. Grafts appeared united to the proximal ulna but bone has resorbed at lower end of graft, with fracture and angulation of distal ulna.

First Operation

The patient was referred to an orthopedist* who initiated treatment by immobilizing the left forearm in a cast for four months. When the cast was removed, there was no evidence of union (Figures 2 C and D), and in May 1955 a grafting procedure with autogenous tibial bone was performed on the left ulna. The pathologic diagnosis of a biopsy specimen from the site of pseudarthrosis was reported to be an "ossifying fibroma."

Postoperatively the arm was immobilized in a long arm cast for six months. After the cast was removed, the child continued to have a painless pseudarthrosis (Figure 3 A and B), minimal deformity, and no disability. For a year after the cast removal, she used the arm normally, being able to "chin" herself with no discomfort. During this time the lateral bowing of the forearm and medial displacement of the wrist became more noticeable. In November 1956 a roentgenogram revealed an eroded area on the cortex of the distal end of the left radius.

The patient was referred to the Mayo Clinic in January 1957. In addition to the café-au-lait spots noted before, she also had a hemangioma on the abdominal wall. Laboratory data, including values for serum calcium, phosphate, and alkaline phosphatase, were normal. Results of funduscopic examination were normal.

Second Operation

On January 22, 1957, the fibrous pseudarthrosis was resected; a single autogenous tibial onlay graft and homogenous iliac bone grafts were applied to the left ulna; and fixation was obtained with special small stainless-steel screws. A biopsy specimen of the cortical erosion of the radius revealed noninflammatory fibrous tissue, and a specimen of the pseudarthrosis site showed fibrous tissue with foci of new bone formation. Postoperatively the patient was placed in a modified shoulder spica.

After four months of immobilization, roentgenograms revealed that the grafts had united at the proximal end of the pseudarthrosis but that bone had been resorbed at the lower end of the graft, with fracture and angulation of the distal end of the ulna (Figures 3 C and D).

Third Operation

Another grafting procedure with a single onlay of autogenous tibial bone was performed on April 30, 1957, four days after the cast was removed following the second operation. The patient was again immobilized in a shoulder spica for three months, after which the arm was immobilized in a long arm cast for six months. Roentgenograms at the time immobilization was discontinued showed satisfactory union, although thinning of the distal ulna was worrisome. The forearm was protected with a leather-lacer cuff for an additional year. The screws were removed in March 1960.

The patient was examined in July 1966, at which time she had minimal clinical and roentgenographic deformity, a one-inch shortening of the left upper extremity, and a full range of motion of the hand, wrist, and elbow (Figure 4).

Discussion

Each of the two cases presented seems to be different from the other and from the two reported previously in the literature. Describing the technique of delayed autogenous bone grafting for surgical correction of congenital pseudarthrosis, J. R. Moore,[3] in 1949, presented a series of eight patients, one of whom had congenital pseudarthrosis of the ulna. The anomaly was long-standing, with obvious deformity noted at birth. In addition to pseudarthrosis of the ulna, the distal ulna was atrophic and the radial head was dislocated.

In 1956 Madsen[1] reported a boy with congenital pseudarthrosis who was first seen by an orthopedist at the age of six years. The forearm deformity had been noted when the boy was two years old. Because of associated congenital deformities, including neurofibromatosis, kyphoscoliosis, spina bifida, and mental retardation, treatment was postponed. When the boy was 10 years old, the bowing of the forearm was increased significantly and the radial head was dislocated. It is interesting to speculate whether, had the deformity been allowed to progress in the two cases presented here, it

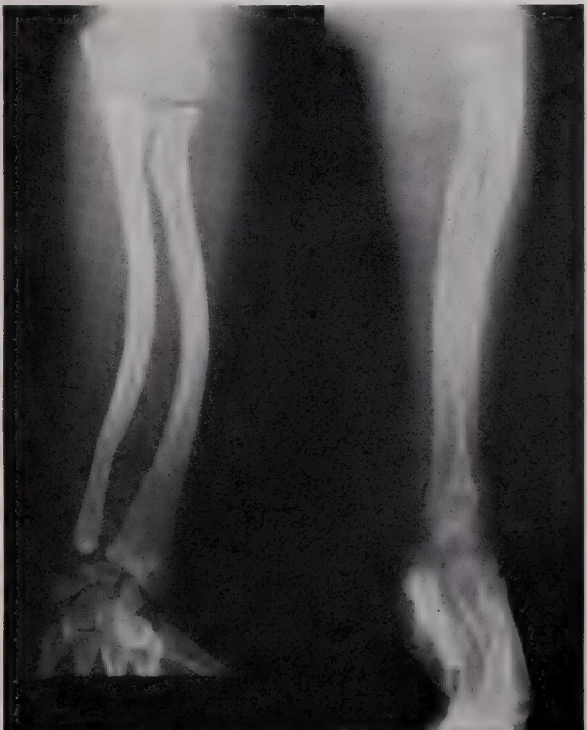

Fig. 4—(Case 2). Patient at 12 years (July 1966). Nine years after third bone grafting procedure of left ulna. There is solid union, with a poorly developed medullary canal.

---

*The initial history, physical examination, x-rays, and first operative report as well as progress reports and x-rays for Case 2 were supplied by Dr. Robert F. Kimbrough, Fort Wayne, Indiana.

too would have eventually dislocated the radial head, resulting in limitation of elbow and forearm motion.

Case 2 illustrates many of the problems seen in congenital pseudarthrosis of the tibia. Adequate immobilization failed to produce union. The first bone graft "melted" away, as is frequently seen when congenital pseudarthrosis of the tibia is treated. The second grafting procedure resulted in a union of the graft to the proximal end of the ulna, but a gradual thinning and fracture of the ulna at the distal end of the graft necessitated a third operation. Even after the third tibial bone grafts united, the surgeon suggested the need for restricted mobility of the extremity and anticipated the delayed development of an intramedullary canal.

Neurofibromatosis

Both of our patients had numerous café-au-lait spots, and one patient (Case 2) had a subperiosteal cyst. Both of these findings have more than a casual relationship with neurofibromatosis. Of the eight patients with congenital pseudarthrosis in Moore's series,[3] seven had café-au-lait spots. In 1950, McCarroll[2] reported the clinical manifestations of 46 patients with congenital neurofibromatosis. Thirty-three of these patients and all of the five patients with congenital pseudarthrosis of the tibia in McCarroll's series had café-au-lait spots. Some investigators[4] believe that café-au-lait spots are diagnostic of neurofibromatosis. Such spots, however, are frequently found in normal people who have no family history or clinical manifestations of neurofibromatosis.

The pathologic diagnosis of the tissue taken from the site of the pseudarthrosis was reported to be "fibrous tissue with foci of new bone formation" in Case 2.

Summary

Two cases of congenital pseudarthrosis of the ulna have been presented. One patient was treated by resection of the short, atrophic distal end of the ulna, which the surgeon believed was acting as a bowstring, resulting in lateral bowing of the forearm and in ulnar drift of the hand. The other patient was treated by bone grafting to obtain solid union at the site of pseudarthrosis.

Early diagnosis and treatment of congenital pseudarthrosis of the ulna may avoid the complication of dislocation of the radial head and will preserve good function of the hand by maintaining satisfactory radial carpal alignment.

School of Salernum

The Priests rule is (a Priests rule should be true)
Those Egges are best, are long, and white and new.
Remember eating new laid Egges and soft,
For every Egge you eat you drink as oft.
—Regimen Sanitatis Salerni

Editor's note: Most delicious here is the jibe at clerical infallibility. Some people might prefer round, brown eggs, but who would care to violate the clergy's injunction that long white eggs are preferable. As for quaffing (water? wine?) each time you consume a soft-boiled egg, was the School serious or did it have its tongue in cheek?

Antibiotic Therapy and Hospital-Acquired Infections*

MYUNG-HI KIM OH, M.D.†
JOHN M. MATSEN, M.D.‡
ARNOLD A. LEONARD, M.D.#
PAUL G. QUIE, M.D.§
Minneapolis, Minnesota

INFECTIONS IN HOSPITALIZED patients continue to be a serious problem, especially on surgical services. This is in part due to the increased application of major surgical procedures in poor-risk patients and medical management with immunosuppressive measures. The reckless use of antimicrobial therapy may also be implicated.[1,2] The spectrum of microorganisms associated with hospital-acquired infections is changing. Endogenous gram-negative bacteria, often demonstrating multiple antibiotic resistance, are now more frequently associated with hospital-acquired infections than previously.[1,4]

This report describes problems with infections on the surgical services of the University of Minnesota Hospital during a six-month period (January 1, 1967 through June 30, 1967). The types of microorganisms most frequently associated with hospital-acquired infections were correlated with certain aspects of antibiotic therapy.

Methods

Six hospital stations with a total of 147 beds were included in this infection survey: four general surgery stations, one orthopedic and one surgical intensive care unit.

During the period of the study all patients considered to have an infection were reported to one of us (A.A.L.) by the station Nurse-In-Charge. Suggestions were made to patients' responsible physicians regarding isolation procedures and the patients were followed until discharge from the hospital. At the completion of the infection survey the hospital charts of all patients considered to have infections during this period were reviewed, and those considered

to have infections defined as "hospital-acquired infections"[5] were included in this report. Urinary tract infections included symptomatic patients with greater than 50,000 bacterial colonies per ml of urine and asymptomatic patients with urinary bacterial colony counts greater than 100,000 colonies per ml.

Results

Infections were diagnosed in 135 patients on the six hospital stations during the period of this study. Of these 135 patients there were 95 with infections defined as "hospital-acquired." Since there were 1,850 patients admitted to these stations during this period, the hospital-acquired infection rate was 5.2%

Wound Infections

The types of hospital-acquired infection included in this analysis are shown in Table 1. As would be expected, since this is a review of surgical services, the most frequent hospital-acquired infections were wound infections. There were 42 patients with two or more infections; therefore the total number of hospital-acquired infections (149) is greater than the number of patients with infections (95).

*Same patient.

associated with hospital-acquired infections (Table 2). It is noted that *Staphylococcus aureus* accounted for more infections (14.8%) than any other single species; however, the enteric gram-negative organisms *E. coli, Pseudomonas, Klebsiella, Proteus* and *Enterobacter* accounted for 39.7% of the hospital-acquired infections. Not included in this analysis were 10 patients with inflammatory lesions which were not cultured and six patients with purulent wound drainage but no growth on culture.

The Antibiotic

The bacterial etiology of infections in these patients was analyzed in regard to the antibiotics they were receiving at the time signs and symptoms of infection developed (Table 3). The patients were divided into groups as follows: Group I—no antibiotics; Group II—penicillin G or semi-synthetic penicillins; Group III—broad spectrum antibiotics (including ampicillin) and combinations of antibiotics. Infections included in Group II and Group III are those in which the culture was taken at least 24 hours after the antibiotic had been started for prophylaxis or treatment of other infections. It is noted that 47% of the patients with gram-positive cocci were receiving broad-spectrum antibiotics and 50% were not receiving antibiotics. Sixty-eight percent of patients with gram-negative bacterial infections were receiving broad-spectrum antibiotics.

Septicemia

There were 19 patients on these surgical services who developed septicemia during the study period (Table 4). Four of the patients with septicemia were not receiving antibiotics when the septicemia was diagnosed, four were receiving penicillin and eleven were receiving broad-spectrum antibiotics. All of seven patients with Pseudomonas septicemia were receiving broad-spectrum antibiotics.

There were 148 patients on whom open-heart operations were done during this period; five of these patients developed sepsis (3.4%). A single bacterial species was recovered from the blood in all of these patients. There were eight patients who received a renal transplant during this study period. Five of these developed sepsis (62.5%). In contrast to the experience with open-heart surgery patients, all of the patients with transplanted kidneys who developed sepsis demonstrated more than one species of bacteria in their blood. One patient had two separate episodes of septicemia, each due to a different type of bacteria (Table 4).

Septicemia with multiple bacterial species also occurred in one patient with a severe burn and in another with multiple internal and external fistulae following traumatic tear of the common bile duct.

Discussion

The problems of hospital-acquired infections in patients continue to be seemingly insoluble in our present state of ignorance. This study confirms observations of others that enteric* bacilli and staphylococci are the major types of bacteria involved in hospital-acquired infections.[1-4,6,7] The rate of infection (5.2%) is in general similar to reports from other university hospitals.[3,4]

The majority of the patients were receiving antimicrobial therapy when bacteriologic evidence for infection was revealed. Other studies have also directed attention to the failure of antimicrobial therapy to prevent infections.[3,4,6,7,8,9]

The observations on antimicrobial therapy in patients with infections and especially with septicemia are clear evidence that infection with certain bacteria occurs and persists despite antibiotics. Strains of *Pseudomonas* and the *Klebsiella-Enterobacter* group were recovered from 13 of the 19 patients with septicemia. All of these patients were receiving antibiotics for at least 24 hours before diagnosis of sepsis. Indeed 11 of the 13 were receiving broad-spectrum coverage. A similar, but less dramatic correlation, was noted in all types of hospital-acquired infections.

These observations do not allow a definite conclusion that antibiotics predispose to hospital-acquired infections since we have no data on non-infected patients. It is obvious, however, that antimicrobial therapy does permit serious infections with opportunistic organisms in susceptible patients.

Men who make money rarely saunter; men who save money rarely swagger. —Bulwer-Lytton

Let's be specific about Campbell's Soups...
and *reducing diets*

calorie content of Campbell's Soups

There are more than 30 million people in America who are overweight. During the next year, you probably will see more than 1,000 of them in your own practice.

One good way to help these patients is to give them a reducing diet based on ordinary eating patterns.

Campbell has prepared a sensible plan for weight control based on ordinary eating patterns. The plan consists of a patient instruction booklet and a set of menus which provide approximately 1,400 calories daily. The menus are balanced to provide the minimum daily requirements of nutrients.

To obtain a supply for your office write to:
Campbell Soup Company, Box 265, Camden, N. J. 08101

Campbell's
SOUP

NOW IS THE TIME... TO GIVE HER TIME WITH OVULEN-21®

Each tablet contains ethynodiol diacetate 1 mg., mestranol 0.1 mg.

The new mother needs time...
to adjust to motherhood,
to give her new baby all the love
and attention he requires.
She needs time for her husband...
and for herself as well...
so that she can come to terms
with the increased cares
and responsibilities now facing her.
She needs time to decide
when she will have additional children
and how many she will have.

OVULEN-21®

Each tablet contains ethynodiol diacetate 1 mg., mestranol 0.1 mg.

GIVES HER TIME

Your prescription for Ovulen-21 gives the new mother time to meet her family's present needs...to plan for her family's future.

She can take Ovulen-21 confidently and comfortably month after month. Its dependability is enhanced by its simplicity of use. A woman needs little or no time to learn the simple Ovulen-21 regimen: three weeks on—one week off. And the automatic record-keeping of the petite, virtually "patient-proof" Ovulen-21 Compack® helps to maintain her schedule...helps put time on her side.

Immediately post partum is the time

It is the time when motivation is highest—when a new mother needs expert advice for the future, so she can space her children and limit her family.

It is also the most opportune time, since she is conveniently present in the hospital, for her to be given both instructions and a prescription.

Non-nursing mothers may begin Ovulen-21 immediately after delivery, on the day of departure from the hospital or at the first postpartum visit, as desired. It is recommended that nursing mothers begin Ovulen-21 four weeks after delivery.

A small fraction of the hormonal agents in oral contraceptive pills has been identified in the milk of mothers receiving these drugs. The long-range effect on the nursing infant cannot be determined at this time.

Indication—Oral contraception.

Contraindications—Thrombophlebitis, thromboembolic disorders, cerebral apoplexy or a past history of these conditions, markedly impaired liver function, known or suspected carcinoma of the breast, known or suspected estrogen-dependent neoplasia, undiagnosed abnormal genital bleeding.

Warnings—Watch for the earliest manifestations of thrombotic disorders (thrombophlebitis, cerebrovascular disorders, pulmonary embolism, retinal thrombosis); if present or suspected discontinue the drug immediately.

British studies reported in April 1968[1,2] estimate there is a seven- to tenfold increase in mortality and morbidity due to thromboembolic diseases in women taking oral contraceptives. In these controlled retrospective studies, involving 36 reported deaths and 58 hospitalizations due to "idiopathic" thromboembolism, statistical evaluation indicated that the differences observed between users and non-users were highly significant. The conclusions reached in the studies are summarized in the table below:

Comparison of Mortality and Hospitalization Rates Due to Thromboembolic Disease in Users and Non-Users of Oral Contraceptives in Britain.

Category	Mortality Rates		Hospitalization Rates (Morbidity)
	Age 20-34	Age 35-44	Age 20-44
Users of Oral Contraceptives	1.5/100,000	3.9/100,000	47/100,000
Non-Users	0.2/100,000	0.5/100,000	5/100,000

No comparable studies are yet available in the United States. The British data, especially as they indicate the magnitude of the increased risk to the individual patient, cannot be applied directly to women in other countries in which the incidences of spontaneously occurring thromboembolic disease may differ.

Discontinue medication pending examination if there is sudden partial or complete loss of vision, or sudden onset of proptosis, diplopia or migraine. Withdraw medication if papilledema or retinal vascular lesions are found.

Since the safety of Ovulen in pregnancy has not been demonstrated, it is recommended that pregnancy be ruled out for any patient who has missed two consecutive periods before continuing the contraceptive regimen. If the patient has not adhered to the prescribed schedule the possibility of pregnancy should be considered at the first missed period.

A small fraction of the hormone agents in oral contraceptives has been identified in the milk of mothers receiving these drugs. The long-range effect on the nursing infant cannot be determined at this time.

Precautions—Pretreatment physical examination should include special reference to the breasts and pelvic organs, and a Papanicolaou smear.

Endocrine and possibly liver function tests may be affected by Ovulen. Therefore, it is recommended that such tests if abnormal be repeated after the drug has been withdrawn for two months.

Pre-existing uterine fibromyomas may increase in size under the influence of progestogen-estrogen preparations.

Because these agents may cause some degree of fluid retention, conditions which might be influenced by this factor, such as epilepsy, migraine, asthma, cardiac or renal dysfunction, require careful observation.

In breakthrough bleeding, and all irregular vaginal bleeding, consider nonfunctional causes. Adequate diagnostic measures are indicated in undiagnosed vaginal bleeding.

Carefully observe patients with a history of psychic depression and discontinue the drug if severe depression recurs.

Any possible influence of prolonged Ovulen therapy on pituitary, ovarian, adrenal, hepatic or uterine function awaits further study.

A decrease in glucose tolerance has occurred in a significant percentage of patients on oral contraceptives. The mechanism of this decrease is obscure. For this reason, diabetic patients should be observed carefully while receiving Ovulen.

Because of the effects of estrogens on epiphyseal closure Ovulen should be used judiciously in young patients in whom bone growth is not complete.

The age of the patient constitutes no absolute limiting factor, although Ovulen therapy may mask the onset of the climacteric.

The pathologist should be informed of Ovulen therapy when relevant specimens are submitted.

Adverse Reactions—A statistically significant association has been shown between use of oral contraceptives and the following serious adverse reactions: thrombophlebitis, pulmonary embolism.

Although available evidence is suggestive of an association, such a relationship has been neither confirmed nor refuted for the following serious adverse reactions: cerebrovascular accidents, neuro-ocular lesions, e.g., retinal thrombosis and optic neuritis.

The following adverse reactions are known to occur in patients receiving oral contraceptives: nausea, vomiting, gastrointestinal symptoms (such as abdominal cramps and bloating), breakthrough bleeding, spotting, change in menstrual flow, amenorrhea during and after treatment, edema, chloasma or melasma, breast changes (tenderness, enlargement, secretion), change in weight, changes in cervical erosion and cervical secretions, suppression of lactation when given immediately post partum, cholestatic jaundice, migraine, allergic rash, rise in blood pressure in susceptible individuals, mental depression.

Although the following adverse reactions have been reported in users of oral contraceptives, an association has been neither confirmed nor refuted: anovulation post treatment, premenstrual-like syndrome, changes in libido, changes in appetite, cystitis-like syndrome, headache, nervousness, dizziness, fatigue, backache, hirsutism, loss of scalp hair, erythema multiforme and nodosum, hemorrhagic eruption, itching. The following laboratory results may be altered by oral contraceptives: hepatic function: increased sulfobromophthalein and other tests; coagulation tests: increase in prothrombin, Factors VII, VIII, IX and X; thyroid function: increase in PBI and butanol extractable protein bound iodine, and decrease in T^3 uptake values; metyrapone test; pregnanediol determination.

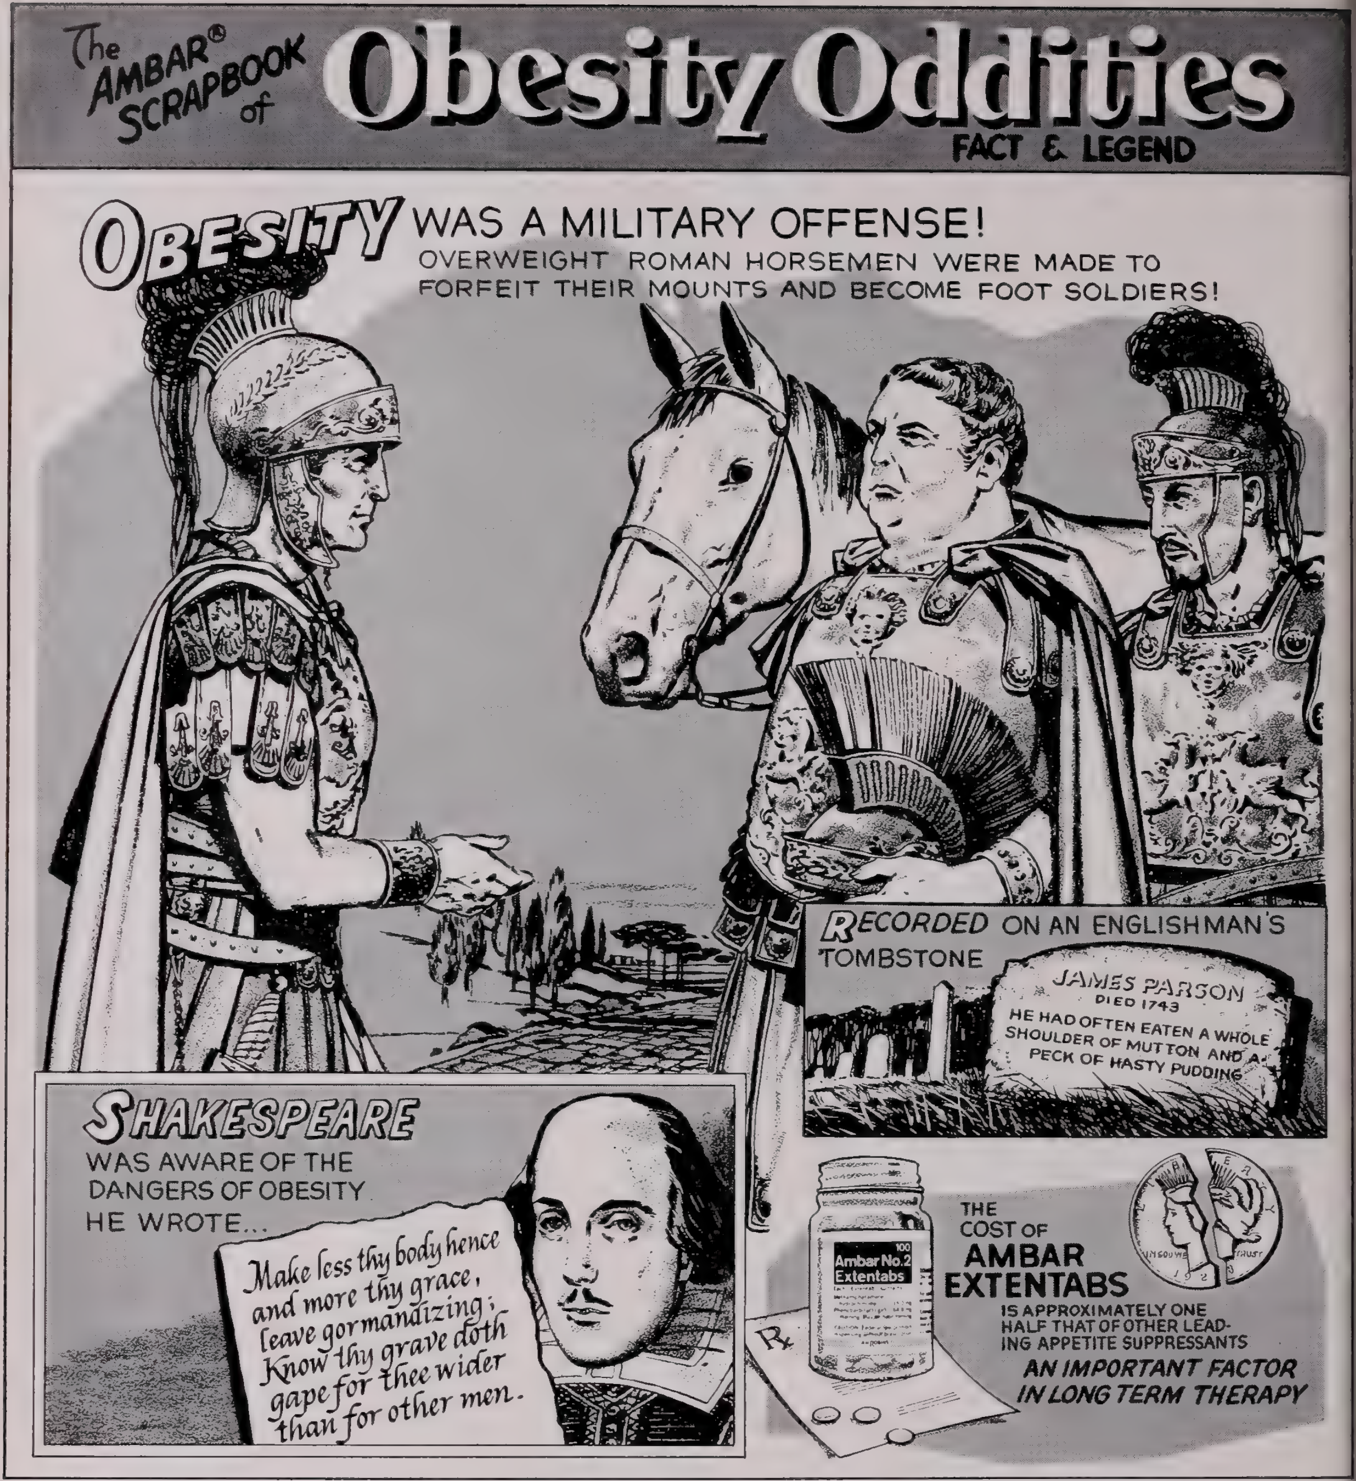
Fifty Years Ago

FIFTY YEARS AGO Dean Lyon could deal with his responsibilities in the Medical School and still have time to relate closely with the faculty and students. I remember him as a warm, genial man, easy to talk to. Not until several years later did Dr. Richard Scammon become involved in the affairs of the medical students and administration. Dr. Scammon supervised my graduate thesis, which involved statistical theory, foreign to me, which he tried (in vain) to clarify. He was an excellent teacher, a liberal thinker and philosopher, well liked by our class. Dr. Jackson was Head of the Department of Anatomy. He was a reserved person with a deep concern about students, which I recognized when I later taught under him in histology and neurology.

It is my duty and privilege this year to write the annual MINNESOTA MEDICINE editorial in honor of the newly elected members of the *Fifty Year Club* whose biographies and photographs appear elsewhere in this issue. [All the physicians—indeed all the citizens of the State of Minnesota—join the editors in honoring this distinguished group of physicians who have contributed so much to the welfare of the people of Minnesota. Ed.]

Names very familiar to me are: Dr. Scott in Physiology, Dr. Herschfelder in Pharmacology, Dr. Downey in Hematology, Dr. Bell in Pathology, Dr. Rowntree in Medicine, Dr. Moore in Surgery, Dr. Sweitzer in Dermatology, and Drs. Hamilton and McKinley in Neurology and Psychiatry. I recall the many legislative sessions Dr. Hamilton had to attend before he succeeded in adding an in-patient service in psychiatry, and it was not until many years later that the in-patient service in child psychiatry was added. The names of Doctors Rodda, Schultz and Sedgwick are fondly remembered, as I became a graduate student in pediatrics.

During our senior year in medicine many in our class served as junior interns in hospitals, depleted of regular interns because of the First World War. We were all in our senior year in the Student Army Training Corps. Those who were junior interns did not have to live in a special building near the campus reserved for this training. Those who served as interns attended lecture classes one or two days a week. We had not been assigned soldier's uniforms; so when we learned one day that we had to wear uniforms in order to be discharged from military service at the close of the War, we were hurriedly outfitted. There was little concern about hat size or sleeve length or trouser size, with the result that when we lined up for inspection, our classmates, the real soldiers, let us know in



The AMBAR® SCRAPBOOK of
Obesity Oddities
FACT & LEGEND
OBESITY WAS A MILITARY OFFENSE!

Ambar No. 2 Extentabs
100
℞
THE COST OF AMBAR EXTENTABS IS APPROXIMATELY ONE HALF THAT OF OTHER LEADING APPETITE SUPPRESSANTS
AN IMPORTANT FACTOR IN LONG TERM THERAPY

CONTROL FOOD AND MOOD ALL DAY LONG WITH A SINGLE MORNING DOSE

AMBAR #2 EXTENTABS®

methamphetamine HCl 15 mg.,
phenobarbital 64.8 mg. (1 gr.)
(Warning: may be habit forming).

One Ambar Extentab before breakfast can help control most patients' appetite for up to 12 hours. Methamphetamine, the appetite suppressant, gently elevates mood and helps overcome dieting frustrations. Phenobarbital, the sedative in Ambar, controls irritability and anxiety... helps maintain a state of mental calm and equanimity. Both work together to ease the tensions that erode the willpower during periods of dieting.

Also available: Ambar #1 Extentabs®—methamphetamine hydrochloride 10 mg., phenobarbital 64.8 mg. (1 gr.) (Warning: may be habit forming).

BRIEF SUMMARY/**Indications:** Ambar suppresses appetite and helps offset emotional reactions to dieting. **Contraindications:** Hypersensitivity to barbiturates or sympathomimetics; patients with advanced renal or hepatic disease. **Precautions:** Administer with caution in the presence of cardiovascular disease or hypertension. **Side Effects:** Nervousness or excitement occasionally noted, but usually infrequent at recommended dosages. Slight drowsiness has been reported rarely. See package insert for further details.

A-H-ROBINS

no uncertain terms what an impression we made.

My senior internship was in internal medicine at the University Hospital, where I worked with Doctors Rowntree, Rizer and Hamilton. This provided an excellent opportunity because of small case loads from which to learn the fundamentals of medicine.

Graduate work in pediatrics brought us close to Doctors Seham, Anderson and Taylor. The outpatient department was in Millard Hall where I initially became acquainted with the role of social case workers. For the first time I learned that a group of professional workers involved themselves deeply with the emotional problems of children and families, and I was profoundly impressed. There was one social worker for the outpatient department in pediatrics, and she was very happy when I expressed a real interest in the behavioral aspects of the child and the family. Part of my fellowship was at the Mayo Clinic where, the year before, Doctors Helmholtz and Amberg headed this new service in pediatrics. The Mayo Clinic, incidentally, had become a part of our graduate school in medicine during our enrollment in the medical school.

The last year of my fellowship was at the Minneapolis General Hospital where Dr. Huenekins was Chief of Staff of Pediatrics. I had admired him as a teacher and looked forward to working with him. It was through his influence that my work in child psychiatry received its main thrust. In his capacity as Director of the Infant Welfare Clinics in Minneapolis, he introduced behavior clinics for the pre-school child and should be identified as one of the pioneers in the study of emotional problems of children in America. He later turned over this work to me and moved into other fields of research that interested him. Much of his career was devoted to introducing pilot studies involving the relationship between physical illness and psychosocial problems.

In the early 1920s, Dr. John Anderson came to the University as Director of the Department of Child Welfare under a Rockefeller Grant. Dr. Florence Goodenough was also a member of the staff and did much of her original research there. During this time Dr. E. K. Lashley was doing a great deal of his research work on the brain, particularly with reference to cerebral localization centers.

In 1923 Dr. Lawson Lowrey brought the Demonstration Child Guidance Clinic to the University for one year. This was under a grant from the Commonwealth Fund and provided us with the knowledge needed to set up the Amherst Wilder Child Guidance Clinic in St. Paul and the Child Study Clinic under the Department of Education in Minneapolis.

In those days interns received no salaries; fellowship stipends in child psychiatry began at $600 a year and went up to $900 in the third year. Two days' hospitalization with the flu in 1924 set me back a total of $18.00. A well built attractive house could be constructed at that time for $9,000. The street-car fare to the University was a nickel, and one could sit in the Minneapolis Orpheum Gallery on 7th Street for 15 cents. To the credit of Spearmint Chewing Gum, even in those days a package of gum cost only 5 cents, as it still does today.

Hyman S. Lippman, M.D.
St. Paul, Minnesota

Not Overpopulated

In the light of vitamin-conscious today, we wonder how mankind actually kept going before we moderns happened along. Consider that orange juice was once used in the West Indies to polish floors; pineapples first sold in London for twenty dollars apiece; in the days of Henry VIII, vegetables were considered unfit for humans and were fed to pigs; lemons were used by the ancient Romans to keep away moths.

Advances in the Management of Hodgkin's Disease*

In recent years the long-held assumptions that Hodgkin's disease is usually of multicentric origin and that patients with this malady are rarely cured have been challenged. Newer approaches to its pathologic classification help the clinician determine which patients with Hodgkin's disease have the best prognosis. Those without systemic symptoms or whose lymph node biopsies show lymphocyte predominance or nodular sclerosis frequently have disease of limited extent. Adequate radiotherapy shows promise of curing a high percentage of such patients. Retrospective studies appear to indicate that a tumor dose of 3,500 to 4,000 rads is necessary to permanently eradicate Hodgkin's disease from any given site, but it is possible that patients with these two more benign forms of the disorder may be cured with a smaller dose of radiation.

Adequate clinical staging of the extent of involvement is essential to rational planning of therapy. Lymphangiography is of great help in detecting occult involvement of the para-aortic and iliac lymph node chains and is now routinely performed in many centers as part of the initial assessment of patients with apparently localized disease, prior to starting treatment.

Patients with more advanced stages have traditionally been treated with single oncolytic† agents. Although worthwhile palliation is often achieved, the remissions are often of short duration. Cooperative therapeutic trials are now in progress, comparing this standard drug treatment with a regimen employing multiple chemotherapeutic agents used in combination or sequence. Preliminary reports indicate a greater rate of prolonged remissions, without a prohibitive increase in morbidity due to drug toxicity, using the multiple-drug technique. Other clinical trials are exploring the usefulness of systemic chemotherapy, followed by focal radiotherapy to areas of residual disease, as initial treatment for patients with disseminated disease.

The physician caring for a patient with Hodgkin's disease can now expect from the pathologist more useful information to aid prognosis. Careful clinical assessment, aided by lymphangiography, will stage the extent of disease as a prelude to treatment planning. Wide-field, high-dose radiotherapy will permanently arrest the disorder in a high percentage of patients with localized disease. Newer concepts of chemotherapy may offer more prolonged remissions for those with disseminated disease. Never has the outlook for many patients with Hodgkin's disease been brighter!

Vascular Compression of the Distal Duodenum*

Compression of the third portion of the duodenum by the superior mesenteric vessels is a well-known clinical entity that is practically never seen by clinicians. In one series of x-ray examinations of the upper gastrointestinal tract one film in 164 revealed such vascular compression. Either this incidence is inordinately high; or the examiners were inordinately astute. Perhaps if the x-ray signs were more diligently searched for in appropriate pictures, more cases would be discovered. Since medical treatment will produce relief in almost all patients, it is important that the condition be discovered when it is present. In the rare case in which surgical treatment becomes necessary, duodenojejunostomy would seem to be a more logical procedure than gastroenterotomy.

No injection after all!

This penicillin produces high, fast levels—orally.

Pen•Vee® K is usually so rapidly and completely absorbed that therapeutic penicillin levels are attained within 15 to 30 minutes. Thus it can often obviate the need for penicillin injections. The higher serum levels produced generally last longer than with those of oral penicillin G.

Indications: Infections susceptible to oral penicillin G: prophylaxis and treatment of streptococcal infections; treatment of pneumococcal, gonococcal, and susceptible staphylococcal infections; prophylaxis of rheumatic fever in patients with a previous history of the disease.
Contraindications: Infections caused by nonsusceptible organisms; history of penicillin sensitivity.
Warnings: Acute anaphylaxis (may prove fatal unless promptly controlled) is rare but more frequent in patients with previous penicillin sensitivity, bronchial asthma or other allergies. Resuscitative (epinephrine, aminophylline, pressor amines) and supportive (antihistamines, methylprednisolone sodium succinate) drugs should be readily available. Other rare hypersensitivity reactions include nephropathy, hemolytic anemia, leucopenia and thrombocytopenia. In suspected hypersensitivity, evaluation of renal and hematopoietic systems is recommended.
Precautions: In suspected staphylococcal infections, perform proper laboratory studies including sensitivity tests. If overgrowth of nonsusceptible organisms occurs (constant observation is essential), discontinue penicillin and take appropriate measures. Whenever allergic reactions occur, withdraw penicillin unless condition being treated is considered life threatening and amenable only to penicillin. Penicillin may delay or prevent appearance of primary syphilitic lesions. Gonorrhea patients suspected of concurrent syphilis should be tested serologically for at least 3 months. When lesions of primary syphilis are suspected, dark-field examination should precede use of penicillin. Treat beta-hemolytic streptococcal infections with full therapeutic dosage for at least 10 days to prevent rheumatic fever or glomerulonephritis. In staphylococcal infections, perform surgery as indicated.
Adverse Reactions: (Penicillin has significant index of sensitization): Skin rashes, ranging from maculopapular eruptions to exfoliative dermatitis; urticaria; serum sickness-like reactions, including chills, fever, edema, arthralgia and prostration. Severe and often fatal anaphylaxis has been reported (see "Warnings").
Composition: Tablets—125 mg. (200,000 units), 250 mg. (400,000 units), 500 mg. (800,000 units); Liquid—125 mg. (200,000 units) and 250 mg. (400,000 units) per 5 cc.

Wyeth Laboratories Philadelphia, Pa.

ORAL PEN•VEE® K

(potassium phenoxymethyl penicillin) Wyeth

Hospital-Acquired Infections*

THE AVAILABILITY of potent antimicrobial agents has resulted in dramatic improvement in the results of treatment of infections which, in the pre-antibiotic era, were associated with high mortality. Lobar pneumonia, erysipelas, streptococcal bacteremia, and bacterial meningitis are often curable infections if properly treated. It has become evident, however, that progress in the treatment of various malignant diseases has resulted in the survival of patients with severe impairment of host defense mechanisms against infections by organisms of the Enterobacteriaceae family. Leukemic patients are especially susceptible to such infections. The danger of a hospital-acquired infection is further enhanced in gravely ill patients by a number of medical technical devices which now have become well-established tools in the diagnosis and treatment of such patients. The indwelling urinary catheter is well appreciated as a potentially dangerous factor in the causation of cystitis, acute pyelonephritis, and bacteremia.

A number of modern devices now commonly used must be looked on as vehicles for the invasion of microorganisms. To name only a few, there are the intravenous plastic needle which often is left in place for too long a time, the intravenous catheter for monitoring of the central venous pressure, and the intravenous wires of the extracorporeal pacemaker. Life-threatening bacteremic episodes may be the result of these otherwise beneficial modern devices. A major problem, potential pulmonary infection, is caused by the use of mechanical respirators. Fatal cavitating pneumonias have resulted from the use of such instruments when contaminated with *Pseudomonas* which easily grows in the nebulizer compartment. The presence of foreign bodies, such as an artificial heart valve, a pacemaker, or a ventriculoatrial shunt catheter, makes it next to impossible to eradicate an infection which has settled in an area immediately adjacent to such a device.

Besides microorganisms belonging to the Enterobacteriaceae, *Staphylococcus aureus* is the main bacterial invader under the circumstances of iatrogenic manipulation. The article by Myung-Hi Kim Ho and associates emphasizes the importance of infections in surgical patients. It is clear that the prophylactic use of antimicrobial agents is a poor substitute for strict aseptic techniques and the careful, regular inspection and monitoring of intravenous sites and of the many types of apparatus which are connected to the acutely and chronically ill patient.

Epilepsia Cursiva Syndrome

Episodic alteration of consciousness associated with running characterizes this syndrome. Sisler and his associates described the condition in nine patients who had either grand mal or psychomotor epilepsy. The running may be coordinated, but it is inappropriate to the reality of the situation. Consciousness may be clouded to a variable degree. Electroencephalograms showed a typical epileptic pattern of disordered rhythm with temporal spikes. Personality types varied, and many of the patients had conflicts in relation to members of their family. Sisler and his associates suggested that these conflicts acted as precipitating factors in the conditions and that the running was an expression of the conflict. Anticonvulsant medication combined with superficial psychotherapy of a reassuring and explanatory type resulted in seizure control and decrease in behavior problems.

Early Recognition of Acute Suppurative Arthritis

EARLY RECOGNITION remains the most important factor in the successful treatment of acute suppurative arthritis. In the small infant this may indeed be difficult. However, early diagnosis and institution of proper antibiotic therapy can be made only if joint aspiration is carried out as soon as septic arthritis is suspected. This should be considered an emergency procedure, just as we consider lumbar puncture for the establishment of a diagnosis and proper therapy of meningitis. However, the procedure should be carried out by persons properly trained in joint aspirations and, therefore, is primarily done by orthopedists.

The duration of antibiotic therapy after the diagnosis of bacterial arthritis has been made remains open to speculation. Gustilo and Amren,* in their article on acute suppurative arthritis in this issue, mention that the oral administration of antibiotics may need to be continued up to 12 months. This may seem excessive, and one wonders whether a diagnostic joint aspiration to determine sterility of the synovial fluid might not be considered to provide a basis for the decision to discontinue antibiotic therapy.

Gunnar B. Stickler, M.D.
Rochester, Minnesota

First Steps in the Development of a Computer-Based Laboratory Information System*

IN RECENT YEARS significant strides have been made in the performance of certain diagnostic procedures. The speed and accuracy of many laboratory tests have been increased by the introduction of automated techniques; however, techniques for processing laboratory data and transmitting them to the medical record remain largely unchanged and are becoming important limiting factors in the continued growth of laboratory technology. As the practice of medicine increases in complexity, the potential usefulness of computers becomes more and more evident, and one of the most promising medical computer applications is in the handling of clinical laboratory data. The more cogent reasons to undertake the development of automated laboratory information systems include: (1) increasing number of laboratory tests per patient work-up, (2) increasing cost and scarcity of medical technicians, (3) increasing role of computers in the performance of laboratory tests, (4) decreasing cost of test performance versus a stable or increasing cost of handling data, (5) centralization of medical services and the growth of regional medical concepts, and (6) increasing demand for medical services consequent to rapidly increasing populations and the extension of health care to larger numbers of people.

Many benefits should accrue from a computer-based laboratory information system; a few are self-evident, but documentation of most must await first-hand experience with functional systems. Monetary benefits in the form of personnel savings have been emphasized and should be realized; however, preliminary analyses indicate that such financial gains will be eroded significantly by the developmental and operational costs of an automated data-handling system. Although the nonpecuniary perquisites are more difficult to quantify than projected financial savings, they promise to exert a more dramatic impact; and they should greatly exceed the expected improvement in transporting a test result. Such

Equipment and supplies for the medical profession since 1919

benefits include: (1) elimination of the need to file, store, and retrieve paper reports; (2) reduction of errors by decreasing manual transcriptions and replacing handwritten, often illegible reports by computer-printed information; (3) making laboratory results immediately available to all potential users; (4) facilitation of quality control by means of computer monitoring; (5) increased sophistication of laboratory test-report formats for clinical, investigative, and educational purposes; and (6) stimulation of technologic growth in the form of increased automation of test procedures.

Scattered attempts are being made to computerize the processing of medical information generated in laboratories; but most operational or developing systems deal with a limited number of tests in one or more laboratories (for example, hematology, biochemistry, or surgical pathology), and few have been designed as components of a complete medical information system. In general, only simple numeric information has been considered, solutions have usually been sought from existing hardware, and the need to handle and maintain some paper records persists. Although studies to date have emphasized the potential advantages inherent in an automated laboratory information system, many important questions remain unanswered, and the first steps in this direction should be cautious ones. The excitement and glamour surrounding a computer-based operation are not adequate justification for its existence. In fact, such a laboratory information system could actually constitute a step backward if it increased the likelihood of error consequent to an additional human transcription or if the test-report format was no longer acceptable to the user. Although the mere presence of a computer in a laboratory can create an aura of accuracy and efficiency, it does not automatically assure fewer errors or increased productivity. If a computer is incorrectly programmed, it will provide incorrect information. Because of the many, varied, and complex laboratory information-handling problems, ready-made information systems are apt to fit poorly and some hand-tailoring is needed.

There is compelling support for the contention that the full benefits of a computerized laboratory information system will be achieved only when it functions on-line as an integral part of a complete medical information system. However, the inchoate state of automated medical information systems demands solutions to many general problems before an integrated holistic* approach becomes practical. In addition to the transport of a report from its place of origin to a file or a user, other problems that must be solved include identification of the test, patient, and specimen; generation of forms; report format development; message verification; computer reliability and backup; quality control of machines and operators; data storage and retrieval for clinical and research purposes; and automatic generation of special reports. It is noteworthy that many of these information-handling problems have complex interfaces with others now facing the medical profession—for example, registration, scheduling, and billing.

There is no longer doubt that computerized laboratory information systems are feasible and desirable. However, the developmental road is rocky and characterized by pitfalls and dead-end pathways; it is already strewn with evidence that some have failed to plan their journey well. The first steps should be taken only after the route has been judiciously chosen; individual requirements and problems must be recognized and carefully defined. It is essential that physicians participate actively in these initial decisions as well as in all phases of the development of computer-based medical information systems, for they alone can delineate the medical problem and determine if a particular solution is medically acceptable. Such participation does not require that the physician possess expertise in electronics or engineering. Lastly, it should be kept in mind that the ultimate goal is a computerized laboratory information system which functions as an integral component of a complete medical information system. One can only speculate as to when this goal will be achieved, but it can be predicted with reasonable certainty that it will be reached; medicine will then realize the full potential usefulness of computers. We must begin now in order to meet successfully the challenges of the future.

Letter to the Editor

In his editorial regarding Dr. Lenggenhagers' paper in the January 1969* issue, Dr. Ronald L. Linscheid wisely suggested the possibility of using a conservative alternate program for treatment.

A modification of this injection technique combining hydrocortisone and Xylocaine can sometimes be more effective than the perfusion of the involved area.

By carefully introducing a 22 needle at the distal palmar crease, the involved tendon can be identified. The tip of the needle is withdrawn a few millimeters and 2 to 3 cc. of the combined solution introduced. Frequently with this technique a palpable and audible "click" can be elicited and the tendon sheath mechanically lysed from the tendon.

By using this hydrostatic technique, a satisfactory lysis may be obtained to afford permanent relief and preclude surgical decompression.

Walter Indeck, M.D.

The Editor's Soliloquy

Social Dereliction

We wonder whether some of the social programs of the Federal Government are not inadvertently raising a breed of parasites. In Kentucky, Medicare and Medicaid make government-financed medicine available to the majority of the populace. Ten physicians last year collected more than $50,000 each from that state for Medicaid service, and the total Medicaid budget for Kentucky for the year was a staggering $48,000,000.

In a village of 800 in Letcher County near the Virginia border a pharmacy was reimbursed $328,290 from the State for filling Medicaid prescriptions, and another pharmacy owned by the same man collected an additional $125,950.

To be sure, patients, not doctors, were determining the frequency of office visits and, though patients do not usually consult a doctor for the common cold, in Kentucky many Medicaid patients did just that at an average cost to the State of about $11.50 per visit.

Some individuals consulted a physician as often as thirty times in two months. The approved government practice is a charge of $10 for the first visit and $5 for each subsequent visit for any one complaint.* And believe it or not, some patients are so extraordinarily versatile as to present a different ailment on each appearance in the doctor's office.

What a fertile field for exploitation: the patient's versatility, the druggist's passivity and the venality of the unscrupulous doctor correlating and operating reciprocally to the benefit of all. Fortunately these isolated instances do not represent the practice of most physicians.

It would be amusing, were the implications not so pernicious, to scan the records of some of the inveterates to see what maladies they reported themselves to be suffering from and what treatments or medication they received. We wonder: did any of them perchance run out of ailments? And if so, did they then run the gamut all over again?

The State of New Mexico has found it necessary to suspend Medicaid because it has run out of money. Two dentists made more than $90,000 each in 1968 for treating welfare patients. One osteopath billed Medicaid for seeing a patient 100 successive days with the charges varying from $6.18 to $81.37 for each visit. Twelve thousand dollars was expended to pay taxi fare for the patients to and from physicians' and dentists' offices.

In Florida a general practitioner was paid $191,000 for Medicare treatments in a single year. A Georgia surgeon collected $131,000. Beginning in June the names and addresses of doctors who made more than $25,000 will be on file in the Senate. Eleven states have so far chosen to stay out of the costly program which is draining state funds at unanticipated rates.†

Of the nineteen million who are on the voluntary Medicare doctor program, which provides a revenue to the Federal government of $1,824,000,000 to pay for doctors' fees, it would be interesting to know what portion of this revenue has been spent for administration of the program.

In the State of Minnesota the Northlands Regional Medical Program, Inc., a federally sponsored organization, was allotted $1,209,910 for the purpose of making surveys into the far corners of the state. They have a full time staff of six coordinating experts, a suite of offices and a board of medical men who receive a small honorarium for each board meeting. As far as anyone can determine over the three-year period of their existence, not one penny has been spent for medical or surgical care of a patient. Contrary to the impression that one gains from reading their bulletins, surely an infinitesimally small number of practicing physicians are of the opinion that we are living in a medically backward state or that even the most remote and inaccessible corners of the state are in dire need of "the latest medical knowledge from research centers" in order that it can be brought to "the patient's bedside."

---

*National Observer, April 28, 1969.

†Science News, 95:497, May 24, 1969.

Such inordinate demand for medical aid is not a demonstration of the need for it but rather an illustration of the abuse to which an intended social benevolence can be put.

The honorable physician and pharmacist know better than to say cynically: If we don't provide the service, someone else will; but such may be the dilemma in which we may eventually find ourselves and from which we may discover it is too late to extricate ourselves. Complacency and apathy are insidious factors that can slowly and silently corrupt the strongest of institutions.

Patients who are demanding and doctors who are prescribing tranquilizers, sedatives, pain-killers, dependency-producing drugs, or even just placebos may be inadvertently propagating a nation of derelicts, like the feudal lords of China who, centuries ago, addicted a nation and literally destroyed it.

Carl O. Rice, M.D.

You May Be Right

IN HIS CURRENT soliloquy the editor has seen fit to cover a wide spectrum of social dereliction with the implication that physicians and patients alike are prone to take advantage of government programs even to the extent of outright cheating. Appropriately, he recognizes that gross abuses under Medicare and Medicaid are restricted to a small minority of physicians.

One may question whether overcharging and unnecessary and excessive service, exposed by government auditing, are confined to government-sponsored plans. To the unbiased observer, the conclusion that this revelation constitutes a grave challenge to the medical profession to police its own house may seem as justified as a condemnation of programs which open up the public till. This conclusion is valid whether the observer believes the basic philosophy of "social insurance" is desirable in whole or in part. Most responsible physicians will probably support legislation which will allow the government to prosecute those vendors of health care who are guilty of fraud in Medicare and Medicaid. Peer review of practices and charges which are questioned by third party carriers is a policy in many medical societies which seems to be working satisfactorily; and utilization review mechanisms, approved now for several years by the American Medical Association, are functioning smoothly in many hospitals.

For those who may be interested, HEW reports that for the fiscal year ending June 30, 1968, administrative costs for Medicare hospital insurance were 2.1% of benefits and for Part B, 10.3%. These figures are comparable to those reported by privately operated hospital and medical insurance programs.

Northlands Regional Medical Program has developed an organization which some may consider a bureaucracy, but at this time most of those who have knowledge of the program see the potential for many desirable accomplishments. All segments of the health care delivery system are in better communication than ever before. In Minnesota the State Medical Association has been represented in every stage of development of the regional medical program, and the voluntary health associations, particularly the Minnesota Heart Association, have led the way in the development of projects which have been well received by practicing physicians. If Minnesota's regional medical program fulfills its obligation, the best available knowledge will emanate from many centers in Minnesota, not just from the "research centers." Those of us who practice medicine in this State have every right to feel that our services are among the very best; but, at the same time, not one of us should be willing to admit that there is no room for improvement or that we cannot learn something of practical importance from the resources available within our State.

The editor laments the fact that no moneys of the regional medical program have been spent on medical or surgical care for patients. Perhaps he should be reminded that the law prohibits such use of funds, a provision for which organized medicine fought.

J. M. Stickney, M.D.
Rochester, Minnesota

Old Doc Hess says: Most evils need no reviewing by a committee, they need only to be quit.

The Heart Besieged

Surgeon Yushkova handled an absolutely astounding case. She performed an operation that has few to equal it in the history of cardiorrhaphy.

While examining a revolver a nineteen-year-old girl inadvertently pressed the trigger. The bullet passed through her heart. Certain symptoms helped to determine that it penetrated the abdominal cavity. Two hours later the girl was put on the operating table.

Yushkova made her first incision. She found the left ventricle pierced, and sutured it. But a gurgling sound in the thorax every time the patient inhaled showed that the pleura was also perforated, and Yushkova sutured it too. The abdominal cavity was opened up next, to extract the bullet. The surgeon found a hole in the diaphragm, and sutured it as well. Then she discovered that the liver was damaged, and sewed it up, and also sewed up the large intestine below the liver, which was also punctured. Finally, Yushkova located and extracted the bullet.

Although the patient's condition had appeared hopeless from the first, Yushkova stubbornly repaired damage after damage. She did not give death the benefit of even the slightest chance.

A month after the operation the young woman was discharged from the hospital.

Treating vaginitis is as easy as AVC

Trichomonads...Monilia...Bacteria

You can depend on AVC—the comprehensive therapy that acts against all three major vaginal pathogens.

Monilia emerging as a major therapeutic problem—

recent studies report increased incidence, attributed in part to the use of oral contraceptives,[1-4] broad-spectrum antibiotics[5-9] and prolonged use of corticosteroids.[7]

recent evidence establishes high rate of microbiological and clinical cure with AVC.[9-11]

Comprehensive—Effective

The published record and more than two decades of clinical experience clearly establish the therapeutic value of AVC in vaginitis/cervicitis and vaginal surgery.

Easy as AVC

Contraindications: Known sensitivity to sulfonamides.

Precautions/Side Effects: The usual precautions for topical and systemic sulfonamides should be observed because of the possibility of absorption. Burning, increased local discomfort, skin rash or other manifestations of sulfonamide toxicity are reasons to discontinue treatment.

Dosage: One applicatorful or one suppository intravaginally once or twice daily.

Supplied: Cream—Four-ounce tube with or without applicator. Suppositories—Box of 12 with applicator.

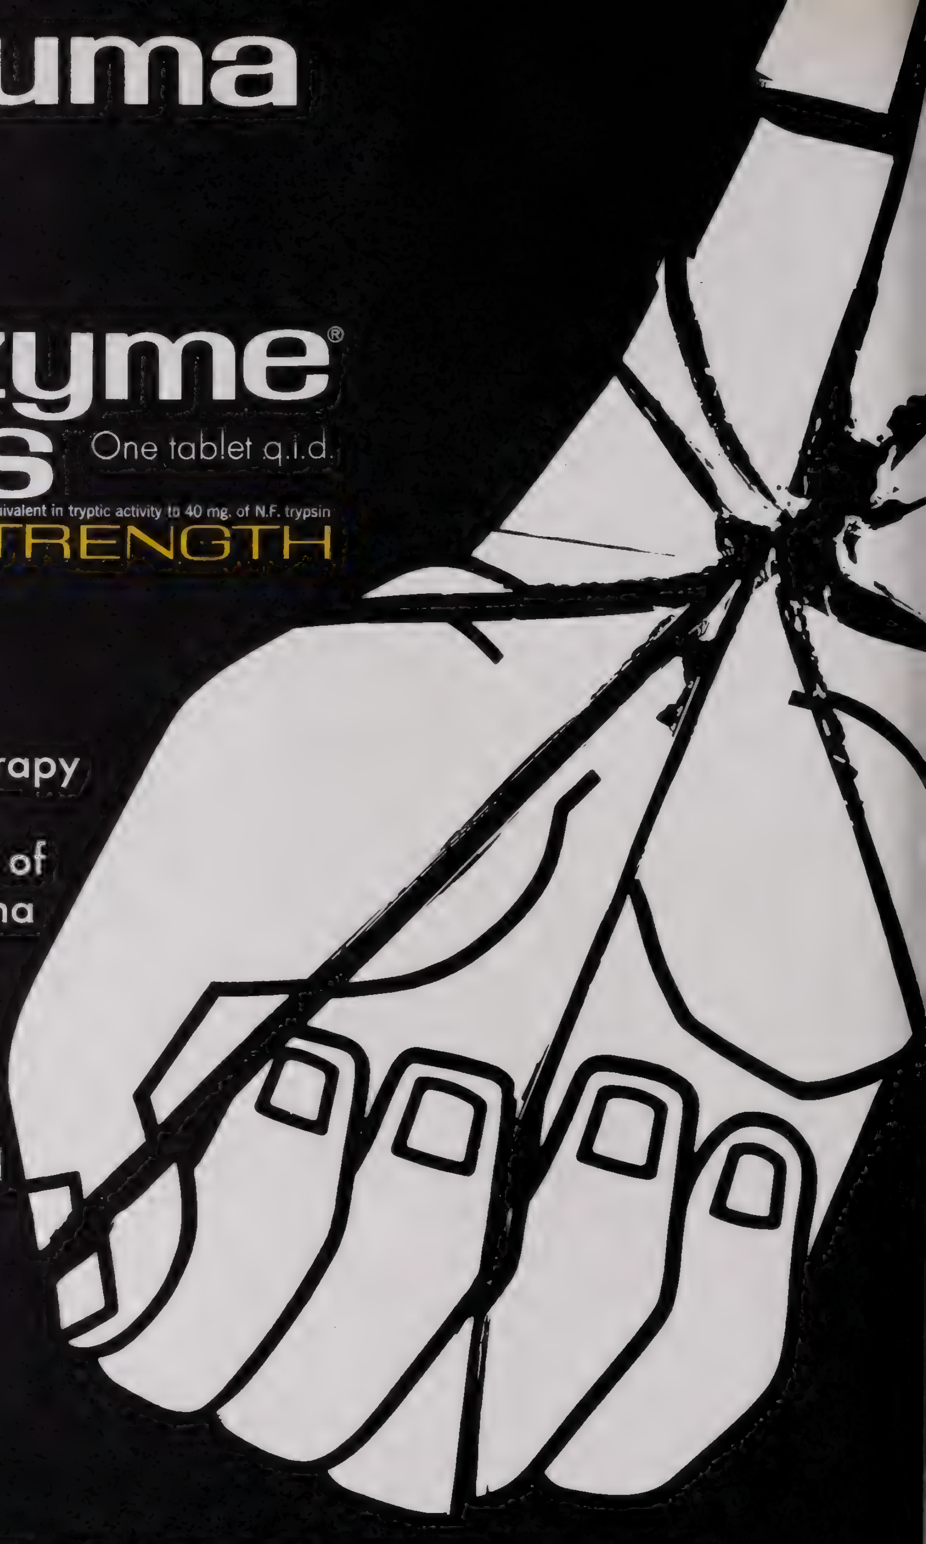
new Orenzyme® Bitabs

One tablet q.i.d.

Trypsin: 100,000 N.F. Units, Chymotrypsin: 8,000 N.F. Units.; equivalent in tryptic activity to 40 mg. of N.F. trypsin

DOUBLE STRENGTH



Proteolytic enzyme therapy specifically indicated for the rapid resolution of inflammation and edema as adjunctive therapy in accidental and surgical trauma.

1 tablet q.i.d. provides recommended therapeutic dose at lower cost.

A FULL DAY'S DOSAGE

Description: ORENZYME BITABS offers the therapeutic effects of trypsin in an oral form as adjunctive therapy for the rapid resolution of inflammation and edema. ORENZYME BITABS is convenient to use, promotes patient cooperation and is ideally suited for maintenance therapy following parenteral trypsin.
Indications: When used as adjunctive therapy for the rapid resolution of inflammation and edema, good results have been obtained in:

☐ Accidental Trauma
☐ Postoperative Tissue Reactions.

Other conventional measures of treatment should be used as indicated. In infection, appropriate anti-infective therapy should be given.
Contraindications: ORENZYME BITABS should not be given to patients with a known sensitivity to trypsin or chymotrypsin.
Precautions: It should be used with caution in patients with abnormality of the blood clotting mechanism such as hemophilia, or with severe hepatic or renal disease. Safe use in pregnancy has not been established.

Adverse Reactions: Adverse reactions with ORENZYME have been reported infrequently. Reports include allergic manifestations (rash, urticaria, itching), gastrointestinal upset and increased speed of dissolution of animal-origin surgical sutures. There have been isolated reports of anaphylactic shock, albuminuria and hematuria. Increased tendency to bleed has also been reported but, in controlled studies, it has been seen with equal incidence in placebo-treated groups. (See Precautions.) It is recommended that if side effects occur medication be discontinued.
Dosage: One tablet q.i.d.

MINNESOTA STATE MEDICAL ASSOCIATION
50

Distinguished Service in Minnesota

The presentation of certificates and pins to Minnesota physicians who have engaged in the practice of medicine for 50 years has become an impressive highlight of each Annual Meeting. According to custom the presentations are made during the course of the Annual Banquet. Few who have witnessed these ceremonies soon forget the setting of such an occasion at which these colleagues with a half century of medical practice to their credit so alertly respond to the roll call.

The custom of honoring Minnesota physicians who have served their patients and communities for a half century was established in 1942. Forty-one physicians were honored at the first ceremony. This group also included those who had passed the 50-year mark prior to 1942.

To be eligible for this award a doctor must have spent the majority of his 50 years practicing medicine in Minnesota.

In 1969 eighteen doctors were added to the membership in this distinguished club.

If I were asked what event in my life had the greatest influence on my medical career I think it would be the receipt of the notification that I had been appointed a Fellow in Medicine by the Mayo Foundation.

The opportunity to take histories of, and do physical examinations on large numbers of patients is an unparalleled one. Especially so when one's tentative conclusions were promptly checked by the results of the laboratory tests, and the opinions and findings of consultants, surgeons and pathologists.

Arlie R. Barnes, M.D.

There were many amusing incidents along the way. In due time I became a member of the graduate committee of the Mayo Foundation. A part of our duties in conjunction with representatives of the Graduate School of the Medical School was to examine candidates for advanced degrees upon the completion of their thesis. A young doctor of Irish descent was being examined as a candidate for the M.S. degree. His minor was pathology. His examiner from the campus of Minnesota was reputed to be a "tough" examiner. His opening question was, "If I gave you a bushel basket full of spleens obtained at necropsy, describe the pathological conditions you might encounter." The candidate, obviously and justifiably nonplused, did not answer for about 15 seconds and then asked, "Doctor, may I be permitted to section those spleens?" When the answer was "Yes," there was a longer and more embarrassing pause and the candidate remarked, "I can't see that it helped me much." After the laughter subsided a less comprehensive question was substituted and the examination went on to a totally satisfactory conclusion.

My contacts with physicians in Minnesota, in societies, at the University or in consultations have been gratifying ones. As I look back over my experience at the Mayo Clinic I can think of no pleasanter environment in which to spend my years as a student and as a practitioner of medicine.

Donald H. Daniel, M.D.

Until his retirement in 1952, Dr. Donald H. Daniel, Minneapolis, was a general practitioner in Minneapolis. He was born in 1892 and graduated from the University of Minnesota in 1920 with an M.D. degree. He interned at Louisville General Hospital in Louisville, Kentucky, from 1919 to 1920. Upon moving to Minneapolis he became a member of the Northwestern Hospital staff.

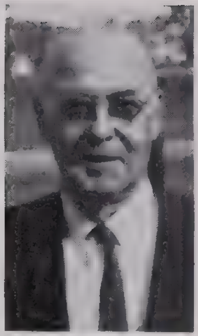
It was in 1908 that a bright-eyed and bushy-haired boy entered North High School in Minneapolis, with the anticipation of becoming a mechanical engineer. After graduating, more definitive anticipation of the engineering career developed upon entering the University, enhanced further by obtaining a job in the drafting room of a manufacturing company which specialized in building sawmill machinery.

Claude J. Ehrenberg, M.D.

For a few months all went well until spring weather provided its enchantment. The drafting room grew increasingly warmer; the endless drawings and blueprints grew increasingly boring. Engineering was fast losing its enchantment. Fortuitously the president of the company had occasion to visit the drafting room and if he was not exasperated upon his arrival, he apparently quickly became so by the pert and saucy responses he received to his inquiries. Shortly thereafter the chief draftsman called the young engineer aspirant to his table and informed the young man that his services were no longer required.

That fall I matriculated at the University of Minnesota undetermined as to any type of career. There I came under the influence of the inestimable and memorable Dr. Sigerfoos during a course in animal biology. From there it was but a short step into the study of medicine.

The founder of the Fairmont Community Hospital, Dr. Victor H. Gardner, Fairmont, was graduated from Leander Clark College, Iowa City, Iowa, in 1917. He received his M.D. degree from the University of Iowa Medical School, also in Iowa City, in 1919. After he interned in obstetrics and gynecology at the University of Iowa Hospital Dr. Gardner practiced in Estherville, Iowa. Before moving to Fairmont he practiced in Dunnell and Waseca.



Victor H. Gardner, M.D.

Retirement from active practice made it possible for me to spend more time with previously neglected hobbies, but it also allowed so much free time that new interests seemed necessary. The opportunity, during all but the winter months, of having almost daily walks with two naturalists and an historian provided an excellent solution to the last problem. A new interest in wild flowers—a field big enough for several life-times of work—pleasantly supplements old interests in bird-watching and trout-fishing, and all these activities supply material for water-color painting. I can't think of a happier way to retire.

Samuel F. Haines, M.D.

Dr. Philip L. Halenbeck, St. Cloud, initiator of the St. Cloud Medical Group, was born in Medicine Hat, Alberta, Canada, in 1891. Forty-one of his 50 years of practice have been spent in St. Cloud where he still practices today. He graduated from the University of Minnesota in 1915 and obtained his medical education at Rush Medical College, Chicago, Illinois. He interned at St. Luke's Hospital in Chicago in general practice, then came to Minnesota and practiced for seven years in Crosby before moving to St. Cloud.

Philip L. Halenbeck, M.D.

Harlow J. Hanson, M.D.

A farm two miles south of Hutchinson in McLeod county was my birthplace in 1892. After preliminary schooling I entered the University of Minnesota for a B.S. degree, then the University of Illinois medical school, and received my M.D. degree in January 1919.

I began my practice in New London. In winter the only means of travel was horses and sleigh. One particular incident which is of particular satisfaction was when a patient was brought to my office (1922) who had gotten his knee in a circular saw while cutting wood. The patella was completely gone; the articular surfaces were nice and smooth except for saw dust. After debridement the muscle and soft tissue were sutured and the knee immobilized. It was quite a satisfaction to meet him on the street afterwards and hear him say: "Doc that knee is just as good as the other one."

I moved to Minneapolis in 1925. Besides my practice I was health officer for the City of Bloomington for 34 years and was awarded a certificate of merit by the city.

I live on the bluff of the Minnesota river in Bloomington with trees and brush, and we have many different birds, pheasants, pileated woodpeckers and a coon who comes up for his favorite food.

Just a remark about the snowmobile craze. I made a snowmobile in 1922 while in my country practice. A Ford car narrowed to fit bob-sled tracks, runners in front and back, and drive shortened for traction. I traveled many miles on it and it did very well. It has all been very satisfactory.

Frank G. Hedenstrom, M.D.

After my licensure in 1919, making me a fledgling doctor, I interned at St. Paul City and County Hospital. I experienced the second wave of the influenza epidemic and the subsequent high incidence of encephalitis. Diphtheria and scarlet fever with their complications were rampant.

The next year I spent in private practice at Braham, Minnesota, with Dr. Charles Swenson, and thereafter returned to the University of Minnesota on a Pediatric Fellowship. Following graduate work in pediatrics, I opened an office in Saint Paul and became involved in the communicable disease section of Ancker Hospital. Here I saw the sharp decline and control of diphtheria, scarlet fever, hemophilus, meningitis, rheumatic fever, and poliomyelitis.

In 1931 we had 189 cases of poliomyelitis and during the peak epidemic of 1946 we had 251 cases of poliomyelitis at Ancker Hospital. I have been on the Pediatric Staff at Gillette State Hospital observing the decline and control of the complications of poliomyelitis, tuberculosis of the skeletal system, and pyogenic osteomyelitis. I was Pediatrician for the Children's Home Society and the Family Nursing Service. I am certified by the American Board of Pediatrics, a fellow of the American Academy of Pediatrics, president of the Northwestern Pediatric Society and president of the Ramsey County Medical Society.

My avocations have been duck-hunting, swimming, and trout-fishing, and I anticipate walking a few more trout streams.

Charles Hymes, M.D.

Dr. Charles Hymes, well-known to his classmates, colleagues and friends as "Charlie," has been in active practice for forty-nine years, first as a general practitioner, and subsequently as a specialist in ophthalmology and otolaryngology.

He married Viola Hoffman, a graduate of the University of Minnesota, in 1930. They have two sons and seven grandchildren. Son Alan is a cardiac and thoracic surgeon, and Richard is a contractor and real estate operator.

Dr. Hymes' thesis for his Master's Degree in Ophthalmology concerned itself with the development and growth of the normal eye. The scleral flap cataract operation and the grooved enucleation implant, as well as the treatment of acute sinusitis with antibiotic solutions by the means of self-induced intranasal negative pressure, are some of his innovations.

Dr. Hymes and his wife enjoy traveling and have been to Europe and Israel several times in the past few years. They have recently returned from a trip to South America with the Minnesota Medical Association.

Don't tell me I look like Truman.

For over thirty years my wife and I have spent July and August in the mountains of Wyoming Jackson Hole and at Woods Lake in Western Colorado at 9500 feet. No one except some of the old timers about Camp had any idea that I was an M.D. Each summer I served as a veterinarian: on a pack trip some fifty miles back in the Wilderness, I operated upon one of our big pack horses which developed a huge abscess on his withers. Vets later told me that fistula on the withers was brucellosis, but apparently my technique was good and no one picked up the infection. To continue the illusion as a veterinarian, I treated cinch and saddle sores and infected wire cuts, checked joints and hoofs in limping horses, removed stones and on one occasion a penetrating horse shoe nail.

I also de-quilled three dogs who were unlucky enough to catch a porcupine. The last was a big Boxer. I blocked his jaws open with a stick on which he chewed very vigorously at first but soon stopped and just held his mouth open while I removed over 75 quills from his tongue, gums, nose and face. After it was over he came over and licked my hands. That is gratitude for you.

Perhaps this is a suggestion for some other poor physician on vacation to help him dodge the tourists seeking free advice.

Thomas J. Kinsella, M.D.

After fifty years of medicine I suppose I should want to retire, but I don't. My work in Child Psychiatry has been so pleasant and gratifying that it is difficult to picture myself leaving the field especially at a time when there is so much to be done. Social workers, clinical psychologists, educators, and many others with a dedicated interest in the social and emotional welfare of children have for forty years been a part of my working family. After thirty-seven years at the Amherst H. Wilder Child Guidance Clinic I am now doing consultation work and teaching at St. Paul-Ramsey Hospital and Medical Center and at Hennepin County Child Welfare.

I have been on the Board of the Joint Commission for Mental Health of Children for the past three years. This has offered me the opportunity of bringing to a head all that I have learned about the emotional needs of children and families, sharing with a large number of colleagues our experiences as clinicians in child behavior. The recommendations we are making to Congress will go a long way towards meeting unmet needs in our society.

Hyman S. Lippman, M.D.

Dr. Peter Arnold Lommen was born in Vermillion, South Dakota, in 1893 and graduated from the University of South Dakota Medical School in 1914. He immediately began his professional education which he completed at Rush Medical College in 1919.

He came to Austin, Minnesota, in January 1920 and has since been active in his professional work and in community service.

He was married to Corena Henry in 1923 and to them were born five children, four sons and one daughter. Two of the sons, Dr. Peter Arnold Lommen Jr. and Dr. Morris Leslie Lommen have followed in their father's footsteps being doctors in the same Lommen Clinic in Austin.

Dr. Lommen's talents and his generosity of spirit are revealed in the following enumeration of activities:

Member and three times president of the Mower County Medical Association; member of the staff of St. Olaf Hospital since its organization and three times president; honored on numerous occasions for medical research studies contributed to professional meetings and periodicals; charter member of Kiwanis, president in 1946, District governor with a record of perfect attendance for 42 years; member and director of Civic Music Association since its organization; member and director of the Chamber of Commerce; member of the first Austin Male Chorus; member and participant in Austin Oratorio Society; received the distinguished service award of the Minnesota Education Association for his integrity and ability to think and act on the basis of facts; nominated to the Hall of Fame in July 1968.

Peter A. Lommen, M.D.

Dr. W. Ray Shannon, Faribault, was one of St. Paul's first pediatricians. Born in 1893 in Duluth, he was a University of Minnesota graduate. Before beginning his practice in pediatrics, he worked in pathology in Montana. His special interest has always been diseases of the newborn and he is best known for his research in cyanosis and tetany in youngsters. He was one of the first staff members of the Family Nursing Service in St. Paul. In 1921 he became an assistant instructor at the University of Minnesota, and upon retirement in 1960 he became an assistant clinical professor of pediatrics there.

Carnot H. Sherman, M.D.

Born in South Dakota and grew up on a farm near the small town of Mt. Vernon. Attended high school in that community and then matriculated at the University of South Dakota as a premedical student and received the B.A. degree. Then finished training at Northwestern Medical School at Chicago.

After internship, went to Arizona for a short while and in 1921 took up practice at Marine-on-St. Croix, Minnesota, which at that time was the tail end of the "horse and buggy" days of the practice of Medicine.

Two years later moved to Bayport, Minnesota. Both of these towns are located on the beautiful St. Croix River and are quite a change from the almost treeless plains of South Dakota.

Six years later took graduate work at the University of Pennsylvania Graduate-School. Then seven years in North Dakota during the "hard" years with dust storms, grasshoppers and drought.

Returned to Bayport to practice and have remained here ever since. Activity has been that of general practice and considerable industrial work with the Andersen Corporation who manufacture windows and with other industries in the town.

Also was Attending Surgeon at the Minnesota State Prison for a number of years and later Chief Resident Physician in addition to private practice.

Adam M. Smith, M.D.

Looking ahead in 1919 when I graduated, 50 years seemed eternity; now looking back, 1919 seems like yesterday. Upon graduation, after a year's internship at Minneapolis General Hospital, I bought a desk and opened an office as a general practitioner. After five years of practice, I was affluent enough to take a trip to Europe, which included three months' study in Vienna. I came home to continue general practice, married and fathered one son.

The trend toward specialization prompted me to go back to Vienna and train in Internal Medicine, after which I returned just in time to fall victim to the 1929-31 depression. As I was sinking for the third time, I acquired a half-time industrial position caring for the 1500 postal employees of the Minneapolis Post Office.

This industrial work, plus my private practice, kept me very busy until 1959 when I retired from the industrial work. Five more years of private practice and I had had it. Turned my office-patients and problems over to my office companion and left on a fast plane to the Orient. The last five years have been five years traveling—reading—working at hobbies.

I have had many experiences and have seen many tragedies. It was always my desire to be understanding in the care of those who were seriously ill.

On the Mesabi Iron Range, when I first came to Minnesota, I received a phone call from a patient who stated that she was very ill. I drove to her home much quicker than she had expected and saw her run from the garden patch into the house. After knocking on the door I heard her call for me to enter, where I found her fully clothed under the covers in her bedroom. When I asked her to explain this strange situation she merely stated that payroll deductions had been made by the mining company and she wanted to get her money's worth.

Cyril M. Smith, M.D.

Dr. Knute A. Sporre, Fergus Falls, came to America from Sweden in his early adolescence. He was graduated from the University of Iowa College of Medicine and has been licensed in both Iowa and Minnesota. A surgeon, Dr. Sporre served southwestern Minnesota and northwestern Iowa in his early practice. Since 1959 he has been on the staff of the Fergus Falls State Hospital and is now chief physician of medical and surgical service there.

Knute A. Sporre, M.D.

Dr. Willard D. White interned at Cook County Hospital after graduating from Rush Medical College in 1918. Upon leaving Cook County Hospital and Chicago, he came to Minneapolis, to be an assistant to Dr. Robert Emmet Farr, an enthusiastic pioneer in local anesthesia. Dr. White assisted him for one year and then became associated with another surgeon, Dr. Archa E. Wilcox, for three years. He was appointed to the surgical staff of the Minneapolis General Hospital (now the Hennepin County General Hospital) after taking a Civil Service Examination and remained on the staff for many years.

In 1924 he married Evangeline Skellet of Minneapolis. They are still happily married and have two sons and eight grandchildren. Dr. White retired at 69. Due to angina he was encouraged to avoid the severe cold and strong winds of Minnesota and has been spending the last several winters in Pompano Beach, Florida where he can enjoy his hobbies of photography, fishing, boating, spectator sports, and just being lazy and being outdoors. He no longer plays regular golf but does a great deal of putting with friends in a weekly tournament. When he returns to Minneapolis in April, or soon thereafter, the ice is out of the lakes, grass is beginning to get green, leaves and blossoms appear, boats are put in the water, the fishing season opens, and there are grandchildren to take fishing and to play with. Dr. and Mrs. White never fail to be thrilled with "the miracle that is spring."

Willard D. White, M.D.

In Appreciation

It is with a feeling of sincere gratitude that we wish to acknowledge the valuable contribution of our technical exhibitors to the success of the Minnesota State Medical Association's 116th Annual Meeting. The Minnesota tradition for outstanding scientific meetings was unquestionably enhanced by these fine exhibits. We frankly recognize that continued participation by our exhibitors in future meetings is essential if we are to maintain this proud tradition. The firms listed below, through their participation in our 1969 Annual Meeting, have demonstrated a meaningful interest in the Minnesota State Medical Association and our Annual Meetings. We sincerely urge that all of our members join with us in expressing our appreciation to these firms and their representatives.

One of these disposables comes prefilled.
Its unit dose – in nonreactive glass
cartridge – is premeasured.
The cartridge is clearly labeled:
drug name, strength, control number.
Even expiration date where appropriate.

You're more confident that the patient gets…

...just what the doctor ordered
with the Tubex Closed Injection System.

Injections with the Tubex system are as easy as 1, 2, 3,

1. Select—from an extensive variety of prefilled Tubex sterile cartridge-needle units.* No multi-dose vials to bother with; no unlabeled syringes to cause confusion.

2. Inject—with a minimum of pain. Thanks to the single-use, stainless-steel needle that's both ultra-sharpened and siliconized. Aspirate simply and conveniently.

3. Throw away—empty cartridge-needle unit. Never used again, it can't transmit infection. And there's no clean-up job.

*For injectables not yet in the ever-expanding prefilled Tubex line, empty sterile cartridge-needle units are available.

Splenectomy for the Diagnosis of Splenomegaly

QUESTION: Is splenectomy ever justified for a patient with splenomegaly in whom a complete diagnostic workup fails to reveal a cause for the findings?

ANSWER: An excellent article bearing on this problem was recently published.* In this series splenectomy was resorted to when other diagnostic measures failed. Fifty-two patients were managed in this way and a diagnosis was established through splenectomy in a majority of them. About one third of the patients were found to have malignant lymphoma, 25% congestive splenomegaly, 34% inflammatory or infiltrative disease; and 6% were found to harbor splenic cysts. This high diagnostic yield rate would seem to recommend splenectomy for the cases about which inquiry is made, providing the patient does not have some associated condition precluding major surgery.

Harold D. Kletschka, M.D.
Montgomery, Alabama

Security

When God made the oyster, He guaranteed him absolute economic and social security. He built the oyster a house, a shell, to protect him from his enemies. When hungry, the oyster simply opens his shell, and food rushes in for him.

But when God made the eagle, He said, "The blue sky is the limit. Go and build your own house," and the eagle built on the highest mountain crag, where storms threaten him every day. For food he flies through miles of rain and snow and wind.

The eagle, not the oyster, is the emblem of America.

Classified Advertisements

Classified advertising rates are twenty (20) cents a word; minimum monthly charge $5.00; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

WANTED: Physician for opening in busy established GENERAL PRACTICE in pleasant out-state location. Salary of $35,000.00 1st year. Write Minnesota Medicine-438, 375 Jackson, St. Paul, Minn. 55101.

GENERAL PRACTITIONER wanted to join well established practitioner in city of 6,000 and serving a population area of 18-20,000. Approximately 70 miles west of Minneapolis-St. Paul. Well-kept clinic building two blocks from the hospital. Fully accredited 85 bed hospital with a Resident Pathologist, Radiological Service, LPN School, X-ray Technician School and complete Physiotherapy Department. Short-term association on salary basis or long-term association with eventual partnership; will accept, consider and appreciate either terms. Please send short resume of your education and previous experience. For further information about this opportunity write: MINNESOTA MEDICINE 431, 375 Jackson, St. Paul 55101.

WANTED: General practitioner to join two young general practitioners in well-established practice in suburban St. Paul. Excellent office space with lab, x-ray, and emergency room. Salary negotiable, with an association leading to early partnership opportunity. Write MINNESOTA MEDICINE 412, 375 Jackson St., St. Paul 55101.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with, early partnership. Write MINNESOTA MEDICINE—289; 375 Jackson, St. Paul, 55101.

CANOE TRIPS—Complete relaxation in the Quetico-Superior Wilderness. Cruise, fish and explore, or base camp on remote lakes. Paddle, motor or fly in. Bring your family—return home completely rested. Cost only $9.00 per diem, $7.00 under 12. Write: Bill Rom, Dept. MM, Canoe Country Outfitters, Ely, Minnesota.

WANTED: Young General Practitioner to join 5 man general practice group. Services of General Surgeon and Radiologist immediately available. College town serving population of 22,000, 30 miles from Twin Cities. Contact Roland M. Hammer, M.D., River Falls Medical Clinic, River Falls, Wisconsin. Phone 425-5322.

WANTED: General Practitioner for staff physician on General Medical Service. Regular hours. Generous fringe benefits, including outstanding retirement program. Nondiscrimination in employment. For further information contact Chief of Staff, Veterans Administration Hospital, Des Moines, Iowa 50309.

THREE PHYSICIANS WANTED: Emergency room at St. Paul, Minnesota, June 1, 1969. 450 beds, expansion 600 beds, 1970. Minimum guarantee $25,000 per year. Work week 28 hours. Contact Thomas W. Votel, M.D. 612-488-6777.

OPPORTUNITY FOR CAREER in occupational medicine with large corporation. Multiple locations. Salary plus fringes. Immediate openings in three locations. Give resume. Write: MINNESOTA MEDICINE—432, 375 Jackson, St. Paul 55101.

THREE MAN group in North West Wisconsin Resort, State Conservation and Retirement Area needs two more physicians adequately to serve their practice. Facilities offered are three-room physician suites, X-ray and lab under AMT technician, RN-only nursing personnel. New accredited thirty-two bed hospital and forty-six bed nursing home. Deer and duck hunting, fishing within five minutes of town. Internist most needed; generalists welcomed. Will meet any reasonable salary request. Partnership after one year. Write: MINNESOTA MEDICINE—365; 375 Jackson St., St. Paul 55101.

ASSOCIATE urgently needed in busy general practice. Excellent clinic and hospital facilities. Salary open. Partnership after 1 year. Klefstad Clinic, Greenbush, Minn. Call collect: Lloyd H. Klefstad, M.D., Tele. 218—782-5275 or 4725.

GENERALISTS AND PSYCHIATRISTS—In accredited progressive 2000 bed mental hospital with approved psychiatric residency training program. Ideal living in active resort community located in Michigan's serene, scenic water-wonderland. Salary $22,550-$30,464 depending on qualifications. (Salary rates effective July 1, 1969.) Unparalleled retirement and fringe benefits. Contact M. Duane Sommerness, M.D., Superintendent, Traverse City State Hospital, Traverse City, Michigan 49684. An equal opportunity employer.

INTERNIST—Six physicians in corporate practice wish to increase service to area by adding general internist to its staff. Fringe benefits are available. Salary open. 150 bed open staff joint commission accredited hospital in community. Write: MINNESOTA MEDIINE—429, 375 Jackson St., St. Paul 55101.

MINNESOTA PROFESSIONAL CORPORATION with fringe benefits wishes to add a general practitioner. Full rights and privileges after one year. Joint commission accredited hospital, open staff. Write: MINNESOTA MEDICINE—430, 375 Jackson St., St. Paul 55101.

The Viewing Box

Atelectasis of Lung following Automobile Accident

THIS 16-YEAR-OLD male sustained trauma in an automobile accident in October, 1967, and three weeks later presented with the chief complaint of shortness of breath. The admission chest film showed nearly complete atelectasis of the left lung (Figure 1). Films at the time of the accident had shown fractures of the left upper ribs, minimal left pneumothorax and some mediastinal air.

What is your diagnosis? (See next page.)

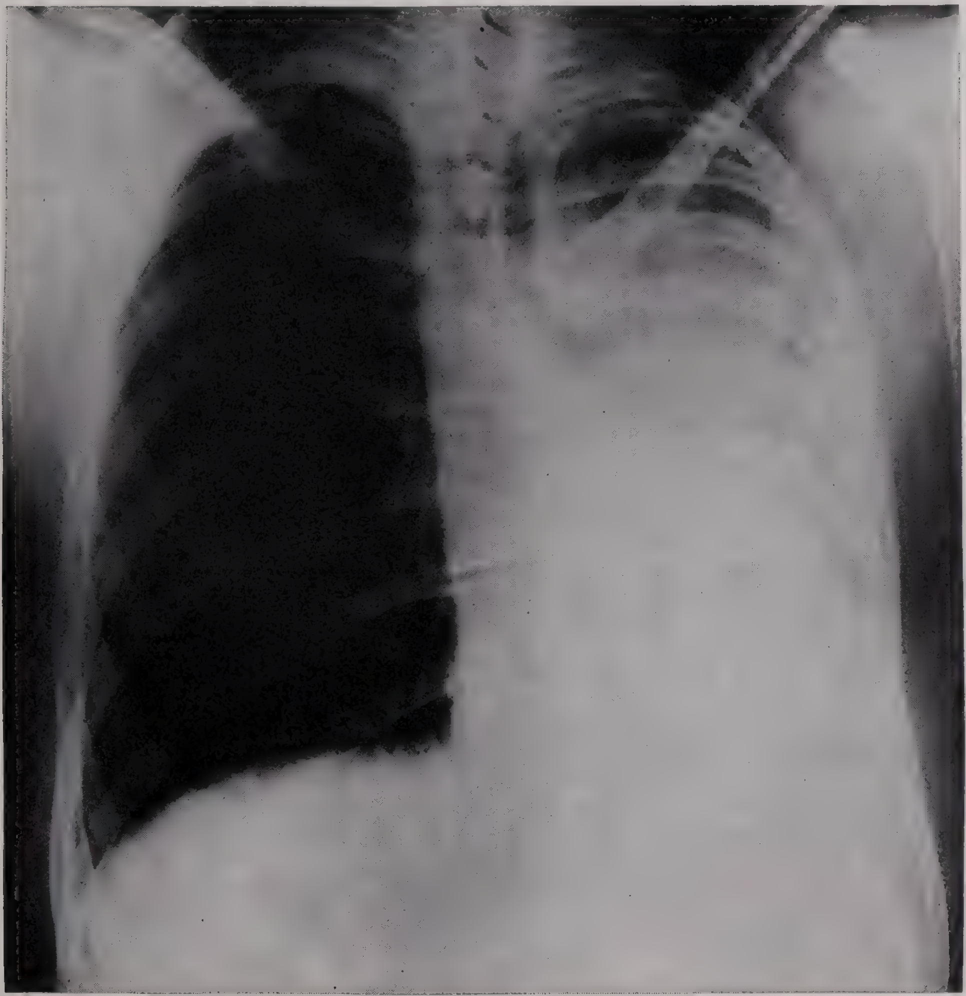

Figure 1

Diagnosis: Rupture of the left main bronchus.

Subsequent planigrams (Figure 2), bronchoscopy and bronchograms (Figure 3) demonstrated a conical occlusion of the left main bronchus, a common sequel to traumatic rupture of the bronchus. Successful surgical repair followed.

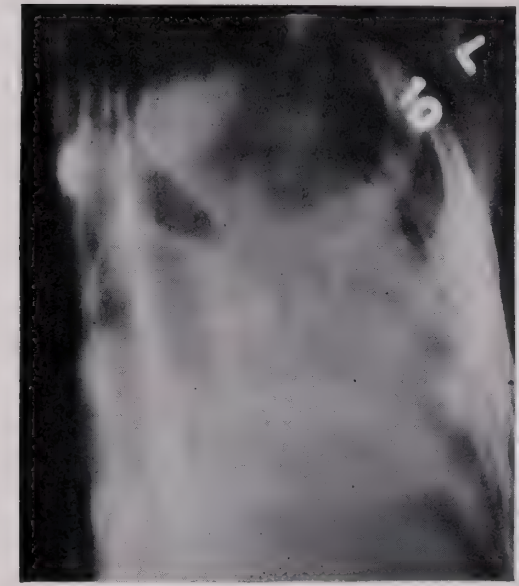

Figure 2

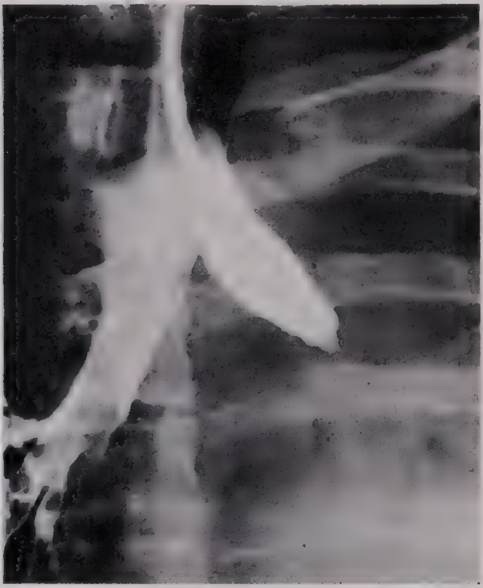

Figure 3

This case clearly demonstrates the need for consideration of possible rupture of the trachea or main bronchus following the ever increasing number of cases of high-impact blunt trauma to the anterior chest wall secondary to vehicular collision. Fractures of the most superior ribs combined with mediastinal air and possibly pneumothorax following anterior chest wall trauma should raise this diagnostic possibility. The effects of bronchial stenosis are usually manifest two to three weeks following the rupture, and if the lumen is completely occluded atelectasis and associated complications will ensue. The narrowing or occlusion is due to the formation of granulation tissue and scarring at the site of the rupture. Prompt diagnosis of traumatic rupture of the trachea or bronchus and subsequent surgical treatment will prevent late complications.

Luther O. Wigdahl, M.D.*
Fridley, Minnesota

Review

Giardia Lamblia as Parasite in Humans

Anton van Leeuwenhoek is credited with the first description of Giardia lamblia in 1681 which he recovered from his own stool.[1,2] It was not until 1859 that Lambl reported it under the name "Cercomonas intestinalis." Finally named in 1915 after Lambl it was placed in the genus Giardia, species lamblia.[3] Giardia possesses a cosmopolitan geographic distribution.[3]

Incidence

Depending on the geographical area as well as the age of the population the incidence varies from 2 to 50%.[2,8,1,7] Infestation is two to three times more common in children who are also more susceptible to its effects.[9,10]

The following three cases will serve to illustrate the clinical symptoms and response to treatment which are fairly characteristic of acute giardiasis.

Characteristics

The trophozoite is rounded anteriorly, tapered posteriorly with a convex dorsal surface, and has a flattened ventral side with a shallow sucking disc near the anterior portion. Four paired flagella arise from superficial organelles on the ventral side. Paired nuclei with single dense nucleoli are readily recognized. Dimensions vary from 9.5 to 21 microns in length, five to 15 microns in width, and 2 to 4 microns in thickness.[4] The trophozoite divides by binary fission.[5]

The cysts appear ovoid or ellipsoidal with a thin, tough wall from which the cytoplasm is characteristically separated. One notes finely granular cytoplasm. Recently formed cysts have two nuclei while the more mature ones have four. The cysts measure 8 to 10 microns in length and 7 to 10 in breadth.[4]

Habitat

The trophozoite characteristically inhabits the duodenum and proximal jejunum where it thrives in an optimum pH of 6.38 to 7.02.[4] Nutrition is felt to be derived from intestinal contents and mucous secretions, although it has been postulated that the trophozoite may feed through attachment of the sucking disc to the microvilli.[3] Zancheck[6] suggested the need for this intimacy with microvilli because he did not find mitochondria or endoplasmic reticulum in the cytoplasm of Giardia lamblia. A carbohydrate rich diet favors the growth of the trophozoite.[3] The attachment to the intestinal mucosa via the sucking disc normally suffices to resist peristalsis. The organism appears to derive random movement through the whipping of the flagella. The cysts are very sensitive to desiccation and are killed at 50°C., but they can survive outside the human body for up to a month.[1,3]

Encystment

Encystment provides for protection and reproduction of the organism.[3] As the trophozoite moves down the intestine it transforms into the cyst.[5] Frankly diarrheal stools yield the trophozoite but encystment occurs more commonly as the liquid stool becomes dehydrated during colonic transit.

Transmission

The cyst usually is transmitted via food and water which has been contaminated with feces through sewage, food handlers, and rarely flies. Man is the natural host and reservoir for Giardia lamblia. Although infestation is more common in children, adults act more frequently as carriers because they are usually asymptomatic.[3] The cyst must be ingested and pass through the stomach before completing its cycle in the duodenum. Transmission requires intimate contact.

Case Reports

Case 1

A 42-year-old white male was admitted to Minneapolis

Veterans Administration Hospital complaining of vomiting, epigastric pain, and mucoid diarrhea. Nine months previously he had been treated for hemorrhagic gastritis but had recurring symptoms since. Three weeks prior to admission the patient had received antibiotics for an episode of pleuritic pain, and subsequently he noted an increase in diarrheal stools from 15 to 20 per day. His alcohol intake had been rather heavy.

Physical Examination

Malnourished, dehydrated, acutely ill. Temperature 101°, epigastric tenderness and RLQ tenderness on rectal examination.

Laboratory

Urinalysis, electrolytes, cephalin flocculation, alkaline phosphatase, fasting blood sugar, and serum bilirubin were normal. Hemoglobin 14 gm/100 ml, WBC 26,000 with left shift. Sedimentation rate 34. BSP retention 22%. Stool and gastric aspirates were guaiac positive. Repeated stool cultures were negative. Barium enema and oral cholecystogram were not remarkable. Roentgenogram of the upper intestinal tract showed a deformed duodenal bulb.

Hospital Course

Intravenous fluids, as well as penicillin and chloromycetin were administered for 15 days. He continued to have mild diarrhea, low grade temperature, and severe headaches. Stool preparations revealed numerous Giardia lamblia. Chloroquine produced no change in symptoms or the parasite. Atabrine produced remission of symptoms and eliminated Giardia lamblia from the stool. The stool remained negative for a nine-month period of follow-up.

Case 2

A 45-year-old white male entered Minneapolis Veterans Administration Hospital with a 12-day history of fever and profuse watery diarrhea (10-12 stools per day). The patient had been treated with Kaopectate and antibiotics by his private physician, but no improvement followed. The patient had lost 10 pounds. He had consumed well water four days before the onset of symptoms.

Physical Examination

Temperature 98.6°, blood pressure 180/80, pulse 72. No acute distress. Diffuse mild tenderness over epigastrum.

Laboratory

Hemoglobin 15.9 gm/100 ml, WBC 9,750/cumm with 80% PMN's, sedimentation rate 18 mm/hr, BUN, FBS, PBI, febrile agglutinins and stool cultures were negative as was the roentgenologic examination of the entire intestinal tract. Giardia lamblia was found in great numbers on stool preparation.

Hospital Course

Atabrine 0.1 gm t.i.d. for five days was followed by complete remission of the symptoms within 72 hours. Follow-up stool examinations were negative.

Case 3

A 24-year-old white male was admitted to Minneapolis Veterans Administration Hospital with a five-week history of up to 10 brown, foul smelling watery stools per day. One month prior to admission, he had returned from Naval duty in Vietnam and the Philippines. He had noted a 35-pound weight loss over a five to six month period, a sensation of "bloating" and cramps which were relieved by expulsion of gas and diarrheal stool, and occasional nausea. The patient associated the onset of symptoms with a visit to Tiajuana, Mexico.

Physical examination was unremarkable.

Laboratory

Hematologic and chemical studies yielded normal results. Roentgenograms of the upper intestinal tract showed an irritable duodenal bulb. Carotene absorption was abnormally low, 57-55 mcg%. Many Giardia lamblia were seen on stool preparation.

Hospital Course

Atabrine 0.1 gm was administered three times daily for five days. Symptomatic improvement followed within 24-36 hours and follow-up stool preparations were negative.

The Clinical Picture

Giardial infestations fail to present a clear-cut and characteristic clinical picture. Patients who have undergone gastrectomy or are malnourished are known to be more susceptible.

Gastrointestinal Symptoms

Usual symptoms are in their order of frequency-diarrhea, abdominal pain, flatulence, abdominal distention, nutritional disturbances, nervous manifestations, anorexia, nausea, vomiting, achlorhydria and anemia.[3] Children usually have severe diarrhea while adults may have diarrhea alternating with constipation.[10] The diarrhea in adults is described as intermittent liquid or soft stools with flocculi or masses of yellow mucus, usually free of blood.[7] Occuring with variable incidence.[12,8,13] Some investigators report that Giardiasis is related to biliary colic and jaundice.[4,11] This has not been borne out as Giardia have only been rarely found in the gall bladder at the time of cholecystectomy (0.7%) and cholecystitis has never been seen in children who have more frequent and more severe infections.[10]

Asymptomatic Individuals

Stool preparations were reviewed in 3187 American soldiers. Giardia lamblia was found in 6.3% of 269 soldiers who had diarrhea, while 5.4% of all others harbored Giardia. A history of diarrhea was elicited in 5.1% of asymptomatic individuals with giardia, while those with a negative history had 5.6%.[7] This type of data has been used by some to show that Giardial infestation in adults may be asymptomatic, while others use this as evidence that Giardia lamblia is not a pathogen.

Rendtorff[14] infected 40 healthy volunteers with Giardial cysts. "Infection" was established in 15 individuals, of whom nine noted a change in stool pattern. An average of 9.1 days elapsed from ingestion to infection (range of six to 15 days).

There remains considerable controversy in the literature as to whether the pathogenicity of Giardia in man is a confirmed entity.[2] It does appear that a commensal relationship exists[8] but it is generally recognized that Giardia may give rise to moderate or intermittent diarrhea and other digestive symptoms and this might be in direct relation to the number of parasites present in the host.[12] The presence of bacteria and malnutrition may act synergistically with Giardia to enhance its pathogenicity.[9]

Malabsorption

There remains some question as to whether Giardiasis causes malabsorption.[11,15] Malabsorption when present, may be attributable to nonspecific abnormalities in the small bowel secondary to protein malnutrition.[16] This is probably true in adults; however, there appears to be no doubt that it can produce malabsorption in children similar to celiac disease which relents with treatment.[2] Yardley[9] gives several possible causes for malabsorption. Giardia may cause direct injury to the intestinal mucosa or it may set up a mechanical barrier due to the massive numbers of parasites. The parasite may cause irritation of the mucosa or alter intestinal motility. Although jejunal mucosal alterations are seen in some patients they are less severe than those of sprue patients.[6,9] There is some evidence correlating malabsorption and the degree of epithelial damage. It would seem that tissue invasiveness is a factor in pathogenesis. Mild clinical cases yield normal biopsies by light microscopy but are abnormal when viewed under the electron microscope. In severe cases both are abnormal.[9]

Invasion of the parasite into the subepithelial lamina propria and submucosa has been demonstrated. Because there are no demonstrable mitochondria or endoplasmic reticulum it has been stated that the Giardia might be rendered antigenically similar to the host so that no inflammatory reaction may result.[17] Electron microscopic studies by Morecki[18] could not confirm invasion. Although he found some in the mucosal cells he concluded invasion was rare and not related to its pathogenicity.

Brandborg[2] states that Giardia was not detected previously in the mucosa because: (1) the staining characteristics are similar or identical to the surrounding tissue, (2) there may be no inflammatory response, and (3) in randomly sectioned tissue only part of the organism is seen. No Giardia were seen in the mucosa of his adult patients who were asymptomatic while mucosal invasion was demonstrated in all those who had diarrhea. Giardia is therefore a significant pathogen although a simple cause-effect explanation does not entirely account for the variability of the lesions reported.[6]

Laboratory Findings

General laboratory findings are generally not helpful in diagnosis.[11] Giardiasis is not associated with a peripheral eosinophilia. Urticaria which relents following treatment has been reported.[19] An altered immune mechanism could be a significant factor in host susceptibility.[20] Hermans[21] described eight patients with dysgammaglobulinemia (virtual absence of IgA and IgM with a moderate increase in IgG), unusual susceptibility to infections, diarrhea with occasional steatorrhea, Giardia in the stools, and nodular hyperplasia of lymphoid tissue in the small intestine. The dysproteinemia persisted after treatment and he felt that Giardia played an opportunistic role.

Diagnosis is based on the demonstration of the parasite in stool preparations. Cysts may be found in formed or semi-formed stool. The trophozoite may be seen in diarrheal stools or duodenal aspirates.[3] Only rarely are the parasites found in the duodenum and not in the stool.[11] Occasionally they may be demonstrated in biopsy material or stained material from duodenal mucus obtained at the time of biopsy. One should check for a history of travel particularly to regions with unsatisfactory sanitation.[9] The diagnosis is usually made by recognition of the cyst in the stool.[3] It must be remembered that frequently there are other parasites present.[12]

Brumpt showed in 1937 an 80% cure of Giardiasis in animals using 1% acridine dye given orally. Galli-Valerio produced a derivative of acridine called Atabrine which has become the treatment of choice.[10,22] The recommended dosage is 0.1 gm t.i.d. for five days in adults, for children the dose is halved.[4] Atabrine (quinacrine) produces 90% clinical and laboratory cure, while chloroquine has shown only 20 to 80% cures.[3] Atabrine is contraindicated in advanced hepatocellular disease.[1] In resistent cases diiodohydroxyquine has been recommended.[9] Boech[23] showed that on treatment the symptoms relent in less than 48 hours, and he considered this response to be diagnostic. Prevention of infection remains a matter of personal hygiene.[7]

Man

Those who collect the significant documents of our age should not overlook the form on which Jan Masaryk, the famous Czech leader, applied for permission to enter the United States of America. In the space opposite "Race" he wrote "Human."—Everywoman.

The average man has 66 pounds of muscle and 3.3 pounds of brain, according to a physician. Maybe that explains a lot of things.—Rotary Realist, La Salle, Ill.

Dulcolax®...so predictable you can almost set patients by it.

Dulcolax works so effectively that the time of bowel evacuation can often be predicted.

Dulcolax tablets taken at night will usually result in a convenient bowel movement the following morning. Dulcolax suppositories generally work within 15 minutes to an hour.

Dulcolax may be given to the aged, pregnant or nursing women, and children. It may be particularly helpful in conditions in which straining should be avoided. The drug, however, is contraindicated in the acute surgical abdomen.

Dulcolax® bisacodyl

Clues to PVD

The geriatric smoker

In studies on peripheral vascular disease—a common by-product of the degenerative aging process—considerable attention has focused on the important role of smoking in the progression of the disease. Although it may not be etiologic, smoking is widely recognized as a prominent contributing factor.[1]

Skin blood flow—significant factor in PVD. Cutaneous digital vasoconstriction caused by nicotine has been observed both in normal subjects and in patients with peripheral vascular disorders.[1,2] Among patients with peripheral vascular disease, however, age and the severity of the disease appear to modify the effects of nicotine. For example, in a study of older patients with *marked* peripheral vascular disease,[3] changes induced by smoking were not statistically significant for the group as a whole. This was explained on the basis of decreased skin reactivity. *Smoking is not permissible in any stage of the disease,* since even "... minimal reduction in blood flow in patients with ischemic limbs may produce a further reduction in tissue nutrition, and thus may be another case of the proverbial straw on the camel's back."[3]

In another study of patients with peripheral vascular disease,[4] the investigators stress that decreased skin blood flow during smoking "... is the factor of most importance to the patient with peripheral vascular disease." *While such patients may adjust to the discomfort of vascular insufficiency in skeletal muscle, decreased skin blood flow may often lead to severe symptomatology.*

More and more physicians have adopted the practice of investigating for peripheral vascular disorder when confronted with a geriatric patient who is a habitual smoker. Once a diagnosis is established, therapeutic measures are directed toward increasing the peripheral circulation and appropriate management of the patient's general medical needs. These include the important safeguards of keeping warm and refraining from smoking.

Professional model posed for illustration.

Important in total management of peripheral vascular disease, vascular spasm or chilblains Roniacol® Timespan®

(nicotinyl alcohol tartrate)

for relief of ischemic symptoms

Convenience of b.i.d. dosage—sustained-release Timespan Tablets usually provide prolonged relief of ischemic symptoms with two doses daily.
Smoothness of onset—the action of Roniacol (nicotinyl alcohol) is smooth and gradual in onset, rarely causing severe flushing.
Selectivity of action—relaxes the musculature of peripheral blood vessels.
High degree of safety—side effects seldom require discontinuation of therapy.

Before prescribing, please consult complete product information, a summary of which follows:
Indications: Conditions associated with deficient circulation; *e.g.,* peripheral vascular disease, vascular spasm, varicose ulcers, decubital ulcers, chilblains, Meniere's syndrome and vertigo.
Caution: Roche Laboratories endorses caution in the administration of any therapeutic agent to pregnant patients.
Side Effects: Transient flushing, gastric disturbances, minor skin rashes and allergies may occur in some patients, seldom requiring discontinuation of the drug.
Dosage: 1 or 2 Timespan Tablets morning and night.
How Supplied: Timespan Tablets—150 mg nicotinyl alcohol in the form of the tartrate salt, bottles of 50.

"All Registered Nurses are Alike"

It stands to reason. They all go through the same training; they all have to pass the same tests; they all have to measure up to the same standards. Therefore, all registered nurses are alike.

That's nonsense, of course. But it's no more nonsensical than what some people say about aspirin. Namely: since all aspirin is at least supposed to come up to certain required standards, then all aspirin tablets must be alike.

Bayer's standards are far more demanding. In fact, there are at least *nine specific differences* involving purity, potency and speed of tablet disintegration. These Bayer® standards result in significant product benefits including gentleness to the stomach, and product stability that enables Bayer tablets to *stay* strong and gentle until they are taken.

So next time you hear someone say that all aspirin tablets are alike, you can say, with confidence, that it just isn't so.

You might also say that all registered nurses aren't alike, either.

Fracture Conference

Shoulder - Hand Syndrome*

Dr. John C. Ivins:†

This case illustrates a most challenging and frustrating symptom complex—the shoulder-hand syndrome.

Dr. Richard H. Turner:‡

This 46-year-old man was involved in an automobile accident on February 21, 1968. He was the only passenger in a one-car accident that occurred when the tire of his car caught on the brim of a curve, and the car went down a 20-foot embankment. He was thrown around inside the car and ended up on the floor on the right front side. At no time was he unconscious; but he remained in the car, unable to move for 20 or 30 minutes, until someone came by and offered to get him out. But he refused the offer because he believed that his back was broken. Finally he was moved by ambulance to the hospital where x-rays demonstrated fractures of both humeri and the pelvis.

In the emergency room he told the attending physician that he had had a myocardial infarction the previous October and that he was presently taking anticoagulants. His arms were put into bilateral Thomas splints at right angles to his body, and he was placed at bed rest, where he remained for four days, during which time his vital signs stabilized. He received a total of four units of blood. At the end of four days his clinical status was stable, and he was transferred to a second hospital 230 miles away. His arms were taken out of the splints and placed on his lap, and he was put on a stretcher. Films taken at the first hospital show the fracture of the right humerus (Figures A and B).

Dr. Ivins:

The film of the left humerus shows a comminuted closed fracture of the proximal third (Figure C). On the right side, there is a closed fracture through the middle third of the right humerus. We do not have the x-rays of the pelvic fracture, but this fracture was considered minor and of no great concern in the treatment of the patient.

---

*Fracture conference held June 3, 1968.

†Professor of Clinical Orthopedic Surgery, Mayo Graduate School of Medicine, University of Minnesota, Rochester and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

‡Resident in Orthopedic Surgery, Mayo Graduate School of Medicine, (University of Minnesota), Rochester, Minnesota.

Dr. Sherwin Goldman:*

For ideal on-the-scene management of a traumatic situation of this kind, I would splint the fracture of each humerus so as to minimize the secondary trauma. These bones should be immobilized so that there is no chance of tearing or laceration of the radial nerve.

Dr. Ivins:

How would you do that?

Dr. Goldman:

Depending on what you have at hand, you could use newspapers, pillows, boards, or anything that was available, or just take a blanket and strap both of his arms to his sides.

Dr. Ivins:

Do you think it is important that whoever does this emergency treatment at the scene of the accident examine the hands and wrists to find out whether there is circulation, motion, and sensation there, or whether there is any injury to the major nerves or vessels?

Dr. Goldman:

If that person was capable of evaluating these factors, it would be fine. Then you would have some idea at the time of what the immediate injury had been. If this could not be evaluated, then just placing the injured person in the best possible position would be desirable.

Dr. Ivins:

Do you think anyone licensed to do this sort of work at the scene of the accident ought to be able to detect loss of function of that kind?

Dr. Goldman:

Well, such a person certainly has had experience feeling pulses, and he can try some simple maneuvers of the hands to determine whether there is nerve damage.

Dr. Ivins:

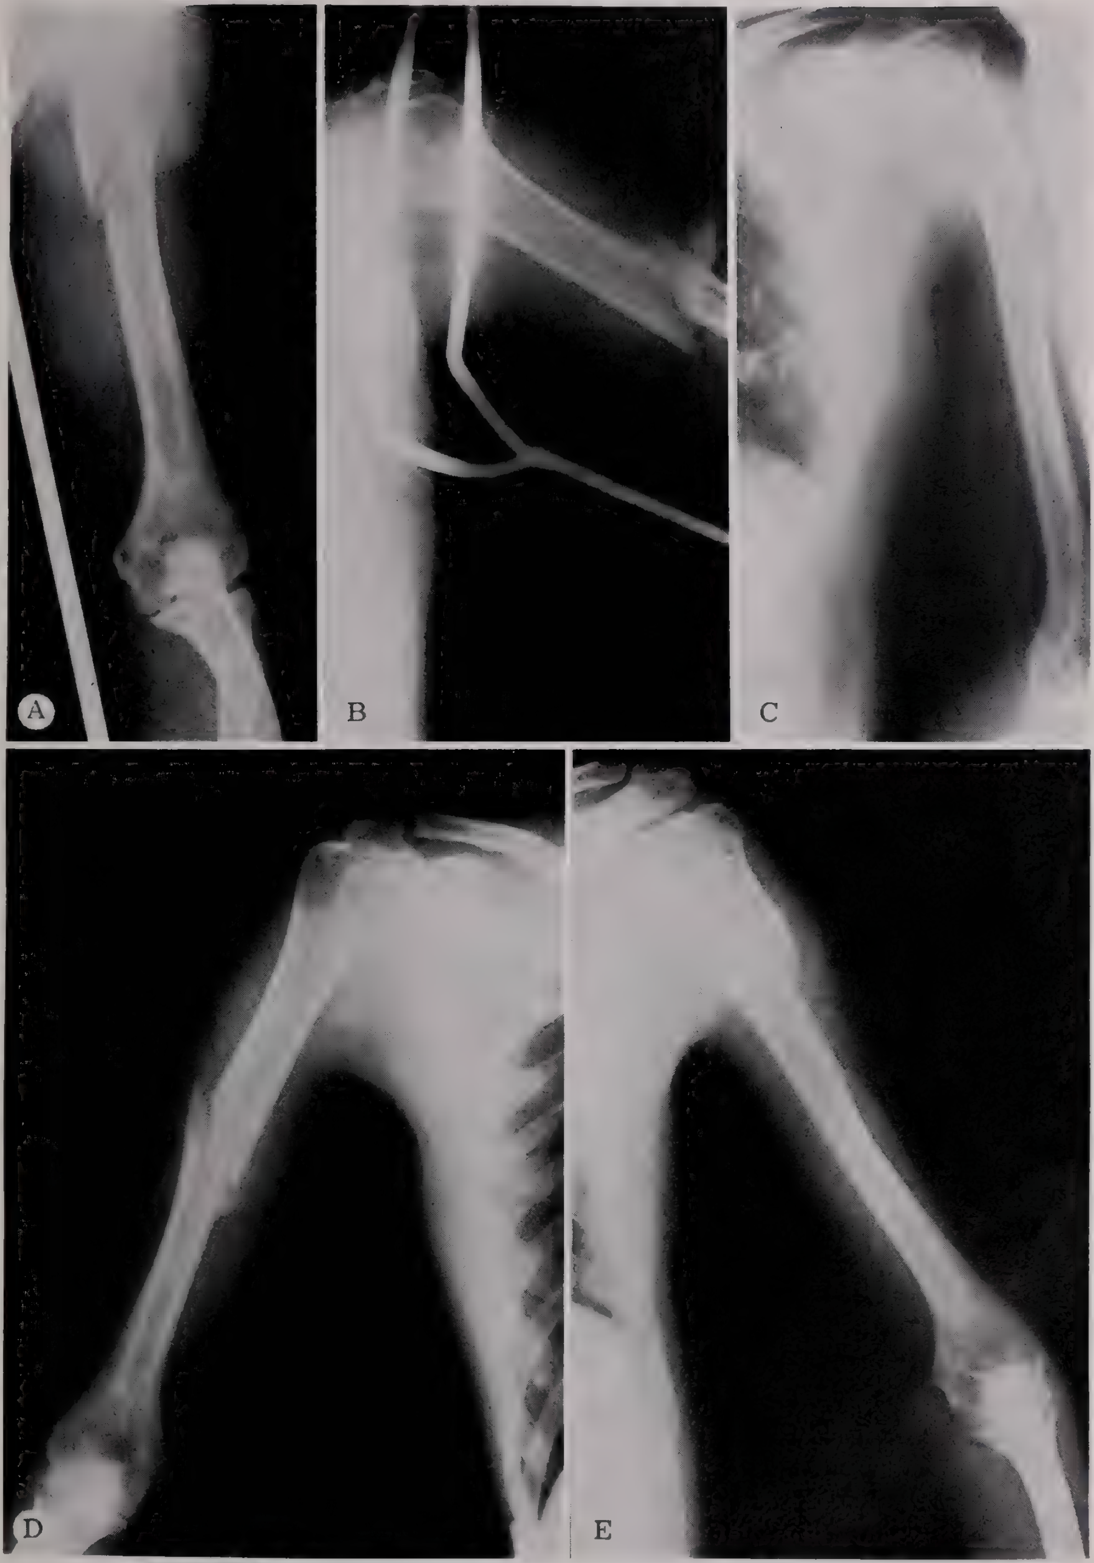
Let us assume that this man has been adequately handled as far as emergency on-site treatment is concerned and he arrives at the hospital with these fractures.

Dr. Goldman:

When he is admitted, I would determine whether his vital signs were stable. There could be some blood loss, and recognition of pelvic injuries involves knowledge about lacerations of the pelvic vessels. First I would make sure that he has an adequate airway. Then I would make sure that his vital signs are stable. After taking his history, you have to consider his anticoagulant therapy and his cardiovascular status against the possibility of continued leakage from the fracture sites. I might be tempted to stop the use of anticoagulants and measure the prothrombin time and blood counts to make sure that these were normal. Then I would turn my attention to the two fractures

---

*Resident in Orthopedic Surgery, Mayo Graduate School of Medicine, (University of Minnesota), Rochester, Minnesota.



Figure—(A) and (B), Right humerus, February 22, 1968, the day after the accident. Fracture of midshaft of right humerus, with slight displacement. (C), Left shoulder, February 21, 1968, the day of the accident. Comminuted fracture of upper end of shaft of left humerus, with slight angulation. (D) and (E), May 7, 1968, when patient was first admitted to our clinic. Right shoulder (D) seems to be healing. Left shoulder (E).

to make sure that the nerve status was intact.

Dr. Ivins:

For the moment let us forget about the problem of the myocardial infarction and anticoagulants. Just assume the blood count and the prothrombin time are normal. We can then turn our attention to the definitive care of the fractures. Dr. Suiter, how would you treat this fracture problem?

Dr. Ronald D. Suiter:*

The fracture on the right, which is toward the lower end, could be treated by the hanging-arm-cast method. The other fracture, which is a little high, may not be controlled by a hanging-arm cast. I think I would just put the arm with the higher fracture at the patient's side and see what kind of position it holds. If the arm holds its reduction while in this position, I would go ahead and apply a Velpeau dressing on it. If it did not hold then I would try to place it in the abducted position.

Dr. Ivins:

As I said, the pelvic fractures were minor and of no significance. We can, therefore, disregard them. Dr. Suiter, you would put the right side in a hanging cast and immobilize the left side with a plaster cast. Is that right?

Dr. Suiter:

I would use either a plaster or Velpeau dressing, depending on how the arm lined up. I cannot see the fracture too well on the second x-ray (Figure C).

Dr. Ivins:

Dr. Peterson, will you give us your opinion of this problem?

Dr. Hamlet A. Peterson:†

Initially, there was a question of a spinal fracture. Was there in fact a spinal fracture?

Dr. Turner:

The pain that the patient felt was from his pelvic fracture. He only thought he had broken his spinal column.

Dr. Peterson:

Essentially, he has fractures of both arms. I would think that it would be better to get him up into a sitting position and probably put each arm in a hanging cast to see how they line up.

Dr. Turner:

The patient was transferred to the second hospital and was placed in bed with his arms out on two chairs. The next morning bilateral long-arm casts were applied. The right arm was laid across his abdomen and traction applied to the left arm. Attendants put traction to the end of the bed, and the patient remained in bed for four or five weeks because of the pelvic fracture. Of course, he would sit up for a short while at meals, and therefore his pelvic fracture was somewhat affected. About the time the casts were put on, approximately the fifth day after the injury, he noted that he could not use his hands as well as he had previously. By the time the casts were removed, he had essentially no function of the shoulder and the joints of his hands, because of the long-term immobilization. He was given physical therapy, which consisted of heat to the joints of both extremities and passive, somewhat forceful, range-of-motion exercises to the point of discomfort. This physical therapy was carried out for four weeks, during which time there was very little improvement. It was then decided that the therapy could be done at home. After one week at home, because there was not much progress, he decided to come to our clinic. This was 11 weeks after the accident. These are the x-rays that were taken on admission (Figures D and E).

---

*Resident in Orthopedic Surgery, Mayo Graduate School of Medicine, (University of Minnesota), Rochester, Minnesota.

†Instructor in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, Minnesota, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester, Minnesota.

Dr. Ivins:

This is 11 weeks after the accident. Dr. Santos, what about the state of the fracture?

Dr. Ray E. Santos:*

It appears to be united, although the fracture line still can be seen. Was he having any pain?

Dr. Turner:

On arrival he was having pain with motion of any joint in his upper extremities. He had 20° of abduction in each shoulder, 20° of flexion in his left elbow, and 30° in his right elbow. There was stiffness in all of his fingers—most severe in his right hand—and swelling of both hands. He had some mild hypesthesia in the thumb and index finger distribution in his right hand, and almost a glove hypesthesia in his left.

Dr. Santos:

Was there motion in the fractures? If so, it is not clinically solid.

Dr. Ivins:

How would you determine that?

Dr. Santos:

By manipulation.

Dr. Ivins:

I did that. I took him to the Section of Diagnostic Roentgenology, and by using the image intensifier I attempted to do just that. The scapulas would move a little on the chest wall, but nothing else would move. Neither the fracture nor the shoulder joint moved. I do not know whether I proved anything, and I do not know that the fractures were solid, but at least there was enough fixation so that it was about equal to the fixation of the shoulder joint.

Dr. Santos:

At this point, if the fracture could not be moved under the image intensifier, I would start mobilizing the adjacent joints, beginning with the shoulder and using physical therapy. You could be a little more aggressive with his elbows.

Dr. Turner:

Passive range of motion to the point of pain tolerance was given.

Dr. Santos:

As far as the therapy is concerned I think that would be about as far as

---

*Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, Minnesota.

I would want them to go.

Dr. Ivins:

The point is that the patient had only passive manipulation of his stiff joints, all of which were extremely painful. He had never had active motion exercises. Throughout this time, he had had frequent, passive manipulations of his injured painful joints which grew steadily worse instead of better. Would anybody like to comment on that?

Dr. William H. Bickel:*

Did they ever check the cervical region of his spinal column?

Dr. Ivins:

His cervical spinal column was all right. By this time he had a classic, chronic, bilateral shoulder-hand syndrome, with almost the textbook picture—swollen hands with all the fingers stiff in extension. There was no motion in any joint in either hand except a tiny amount in all fingers except the right index finger, which could not be flexed at all.

Dr. Vu V. Nguyen:†

Since Steinbrocker's[1] first description of the natural history of the shoulder-hand syndrome in 1947, as a specific type of reflex sympathetic dystrophy, there has been voluminous literature reporting various causes and pathophysiologic mechanisms of this condition which has been described under many different names: shoulder-arm syndrome, posttraumatic dystrophy, posttraumatic spreading neuralgia, and neurotrophic rheumatism (in Europe exclusively).

Etiology

The exact cause of the shoulder-hand syndrome has not been satisfactorily determined. It has been postulated that afferent stimuli from trauma to the upper extremity, from trauma to the heart (myocardial infarction), or from trauma to the central nervous system (stroke or brain tumor) cause widespread disturbances of sympathetic centers in the cervical cord. These disturbances increase sympathetic outflow and cause pathologic changes in the extremity involved. In turn, these changes result in pain, which acts as a feedback system to perpetuate the sympathetic outflow.

If this outflow can be blocked or modified long enough to allow reversal of the disease, the vicious cycle can be broken and the patient will recover. The sympathetic overactivity provokes continuous vasospasm of the terminal arterial channels. Capillaries and venules become distended with sluggishly flowing blood lacking the propulsive pressure transmitted from the arterioles. This is the basis for the cyanosis and coldness of the hand. Slowly moving blood develops a low pH, which promotes dissolution of mineral salts from bone. Arteriolar spasm effects a relative ischemia of all tissues. As a consequence, increased permeability of capillaries and venules permits diffusion of plasma and its fibrin content into the tissue spaces, manifested clinically as edema. Fibrin deposition is followed by fibrosis replacement, which accounts for the thickening of the palm. In addition, the mobility of joints is restricted and never fully recovered. An accurate diagnosis can be made in a high percentage of cases by application of the criteria enumerated by Steinbrocker[1] in his original paper.

---

*Professor of Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester, and Consultant, Section of Orthopedic Surgery, Mayo Clinic, Rochester.

†Resident in Orthopedic Surgery, Mayo Graduate School of Medicine (University of Minnesota), Rochester.

Course

The course of the disease is divided into three stages[2] of from three to six months each, though the entire course may be telescoped into a matter of a few weeks.

In the first stage, the shoulder has various degrees of pain, with restriction in all ranges of motion, especially in abduction and external rotation. The hand is swollen, with thickened palmar fascia and cutaneous hypesthesia. Vasomotor instability is manifested by a purplish, reddish mottling of the skin. The fingers have thickening of the dermis and are held in moderate flexion, with severe increase in pain on attempts to further flex or extend them.

In the second stage, there is increased tightness of the shoulder, with possible atrophy of the muscles. Roentgenograms may show patchy osteoporosis of the head of the humerus and early osteoporosis of the wrist and fingers. Edema is decreased in the skin, which is shiny and dystrophic with obliteration of the skin creases in the hand (sclerodactylic type).

In the third stage, which may last for years, there is dissipation of pain in both the hand and the shoulder, with residual contracture. The contracture of the fingers can be so severe that the extremity may be completely useless.

Treatment

Treatment must be psychologic and physiologic. Patients with the shoulder-hand syndrome usually are very distressed and in need of sympathy. The physiologic treatment must aim at blocking the sympathetic overactivity and correcting the consequences of the sympathetic dystrophy (pain, stiffness, osteoporosis). The patient must be given adequate analgesic medication combined with physical therapy of the extremity involved (range of motion exercise, active exercises with stretching of shoulder in abduction, dynamic splinting of the fingers). Some authors advise heat, massage, and local injection of cortisol (compound F). Cortisone can be given during a period of 10 days. Blocking of the sympathetic outflow to the extremity can be realized by different sympatholytic medications or by local blocking of the stellate ganglion with an anesthetic agent.

When the symptoms of the shoulder-hand syndrome are severe or chronic, sympathetic denervation of the upper extremity may be indicated. In 1922, Bruning[3] reported that excision of the stellate ganglion was more effective than periarterial sympathectomy. Complications after stellectomy* include Horner's syndrome, which may be transient or permanent. Thus, to avoid this complication, sympathetic denervation has been extended progressively to removal of the first three thoracic ganglions, especially T-2. Approach to these ganglions can be made anteriorly, posteriorly, transpleurally, or extrapleurally. In 1954, Atkins[4] credited Goetz and Schulze of Cape Town, South Africa, with being the first to use the transaxillary approach to cervicothoracic sympathectomy.

Dr. Ivins:

I feel that there was a clear indication in this situation to do an open reduction on the right side. I think that arm would have been functionally normal. I say that without knowledge about the index finger. As Dr. Turner pointed out, the patient had some hypesthesia on the dorsum of his first web space on the index finger and the dorsum of his thumb. If this had been recognized at the time, I would have been more in favor of doing an open reduction. I would like to have some comment on this. Do you think the index finger is related in any way to median nerve injury at the fracture site?

---

* See Test Your Word Score Page 1087.

Dr. Edward D. Henderson:*

I do not see how. I do not know why the index finger on the right was so much more severely involved. And I do not see how you can injure the median nerve that high without having more evidence.

Dr. Ivins:

Any other comments or questions about the shoulder-hand syndrome as illustrated in this case?

Dr. Henderson:

Have your patients been relieved by the drugs that are supposed to block the sympathetics?

Dr. Ivins:

I have never used any of those drugs. The only other approach to this problem in my experience was some years ago when we used to give steroids orally. But I was never as impressed with that program as with a skillfully performed stellate ganglion block.

Walk of Life

"Exercise," the doctor said,
"I certainly suggest.
And studies in the field of medicine say walking's best.

"It helps the breathing, helps the heart,
Improves the muscle tone.
And now excuse me, must depart."
And he hung up the phone.

And walked, yes walked and walked, it's true,
With healthful stride. How far?
From where he had been sitting to his car.

—Richard Armour: The Medical Muse, 1963.

In the complex picture of moderate to severe anxiety...

there is a new reason for prescribing Mellaril (Thioridazine HCl)

effectiveness in mixed anxiety-depression

Long recognized for its usefulness in the treatment of moderate to severe anxiety, Mellaril is now also known to be effective against mixed anxiety-depression.

Often the symptoms of anxiety states are difficult to sort out—even with the most careful probing. The patient may manifest symptoms of agitation, restlessness, insomnia, somatic complaints. But what of the depression that may be mixed in the total picture? It is reassuring to know that Mellaril may be prescribed—with strong possibilities of success—when there is anxiety alone or a mixture of anxiety and depression.

Before prescribing or administering, see Sandoz literature for full product information, including adverse reactions reported with phenothiazines. The following is a brief precautionary statement.
Contraindications: Severe central nervous system depression, comatose states from any cause, hypertensive or hypotensive heart disease of extreme degree.
Warnings: Administer cautiously to patients who have previously exhibited a hypersensitivity reaction (e.g., blood dyscrasias, jaundice) to phenothiazines. Phenothiazines are capable of potentiating central nervous system depressants (e.g., anesthetics, opiates, alcohol, etc.) as well as atropine and phosphorus insecticides. During pregnancy, administer only when necessary.
Precautions: There have been infrequent reports of leukopenia and/or agranulocytosis and convulsive seizures. In epileptic patients, anticonvulsant medication should also be maintained. Pigmentary retinopathy may be avoided by remaining within the recommended limits of dosage. Administer cautiously to patients participating in activities requiring complete mental alertness (e.g., driving). Orthostatic hypotension is more common in females than in males. Do not use epinephrine in treating drug-induced hypotension. Daily doses in excess of 300 mg. should be used only in severe neuropsychiatric conditions.
Adverse Reactions: *Central Nervous System*—Drowsiness, especially with large doses, early in treatment; infrequently, pseudoparkinsonism and other extrapyramidal symptoms; nocturnal confusion, hyperactivity, lethargy, psychotic reactions, restlessness, and headache. *Autonomic Nervous System*—Dryness of mouth, blurred vision, constipation, nausea, vomiting, diarrhea, nasal stuffiness, and pallor. *Endocrine System*—Galactorrhea, breast engorgement, amenorrhea, inhibition of ejaculation, and peripheral edema. *Skin*—Dermatitis and skin eruptions of the urticarial type, photosensitivity. *Cardiovascular System*—Changes in the terminal portion of the electrocardiogram have been observed in some patients receiving the phenothiazine tranquilizers, including Mellaril (thioridazine hydrochloride). While there is no evidence at present that these changes are in any way precursors of any significant disturbance of cardiac rhythm, several sudden and unexpected deaths apparently due to cardiac arrest have occurred in patients previously showing electrocardiographic changes. The use of periodic electrocardiograms has been proposed but would appear to be of questionable value as a predictive device. *Other*—A single case described as parotid swelling.

Mellaril®
(Thioridazine HCl)
25 mg. t.i.d.

for moderate to severe anxiety and mixed anxiety-depression

- Neo-Synephrine® (brand of phenylephrine) HCl, 0.5% (adult strength), decongestant
- Thenfadil® (brand of thenyldiamine) HCl, 0.1%, antihistamine
- Zephiran® (brand of benzalkonium as chloride, refined) Cl, 1:5000, antiseptic wetting agent

Treatments with NTz should be repeated every three or four hours as needed. NTz is for temporary relief of nasal symptoms and overdosage should be avoided. Available in squeeze bottles of 20 ml. and 1 oz. bottles with dropper.

Winthrop Laboratories, New York, N.Y. 10016 (1289M

When it's more than a bad cold

your patient can feel better
while she's getting better

Achrocidin®

Tetracycline HCl—Antihistamine—Analgesic Compound

Each tablet contains: ACHROMYCIN® Tetracycline HCl 125 mg.; Phenacetin 120 mg.;
Caffeine 30 mg.; Salicylamide 150 mg.; Chlorothen citrate 25 mg.

In tetracycline-sensitive bacterial infection complicating respiratory allergy, ACHROCIDIN brings the treatment together in a single prescription—prompt relief of headache and congestion together with effective control of the organisms frequently responsible for complications leading to prolonged disability in the susceptible patient.

For children and elderly patients you may prefer caffeine-free ACHROCIDIN Syrup. Each 5 cc contains: ACHROMYCIN (Tetracycline) equivalent to Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Salicylamide 150 mg.; Ascorbic Acid (C) 25 mg.; Pyrilamine Maleate 15 mg.

Contraindications: Hypersensitivity to any component.

Warning: In renal impairment, since liver toxicity is possible, lower doses are indicated; during prolonged therapy consider serum level determinations. Photodynamic reaction to sunlight may occur in hypersensitive persons. Photosensitive individuals should avoid exposure; discontinue treatment if skin discomfort occurs.

Precautions: Drowsiness, anorexia, slight gastric distress can occur. In excessive drowsiness, consider longer dosage intervals. Persons on full dosage should not operate vehicles. Nonsusceptible organisms may overgrow; treat superinfection appropriately. Treat beta-hemolytic streptococcal infections at least 10 days to help prevent rheumatic fever or acute glomerulonephritis. Tetracycline may form a stable calcium complex in bone-forming tissue and may cause dental staining during tooth development (last half of pregnancy, neonatal period, infancy, early childhood).

Adverse Reactions: *Gastrointestinal*—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. *Skin*—maculopapular and erythematous rashes; exfoliative dermatitis; photosensitivity; onycholysis, nail discoloration. *Kidney*—dose-related rise in BUN. *Hypersensitivity* reactions—urticaria, angioneurotic edema, anaphylaxis. *Intracranial*—bulging fontanels in young infants. *Teeth*—yellow-brown staining; enamel hypoplasia. *Blood*—anemia, thrombocytopenic purpura, neutropenia, eosinophilia. *Liver*—cholestasis at high dosage.

Upon adverse reaction, stop medication and treat appropriately.

now she can cope...

thanks to

Butisol SODIUM®
(SODIUM BUTABARBITAL)

the "daytime sedative" for everyday situational stress

When stress is situational—environmental pressure, worry over illness—the treatment often calls for an anxiety-allaying agent which has a prompt and predictable calming action and is remarkably well tolerated. BUTISOL SODIUM (sodium butabarbital) meets this therapeutic need.

After 30 years of clinical use . . . still a first choice among many physicians for dependability, safety and economy in mild to moderate anxiety.

Contraindications: Porphyria or sensitivity to barbiturates.

Precautions: Exercise caution in moderate to severe hepatic disease. Elderly or debilitated patients may react with marked excitement or depression.

Adverse Reactions: Drowsiness at daytime sedative dose levels, skin rashes, "hangover" and systemic disturbances are seldom seen.

Warning: May be habit forming.

Usual Adult Dosage: As a daytime sedative, 15 mg. (¼ gr.) to 30 mg. (½ gr.) t.i.d. or q.i.d.

Available for daytime sedation: Tablets, 15 mg. (¼ gr.), 30 mg. (½ gr.); Elixir, 30 mg. per 5 cc. (alcohol 7%).

BUTICAPS® [Capsules BUTISOL SODIUM (sodium butabarbital)] 15 mg. (¼ gr.), 30 mg. (½ gr.).

Otolaryngology Clinics

The Diagnostic Management of the Neck Mass*

THE HEAD AND NECK are most accessible for examination with little discomfort to the patient. By utilizing a few basic principles, the physician may quickly arrive at the best diagnostic probabilities in a patient with a neck mass.

The history is the first clue to diagnosis. Previous operations should be documented. To be considered in cervical swellings are the growth pattern, the presence of pain or hoarseness, neurological deficit, and concomitant systemic illness. Taking the history should include inquiries into problems of dysphagia, nasal obstruction or drainage, diplopia, hearing loss and tinnitus. The method and duration of alcohol and tobacco use are pertinent, because oropharyngeal malignancy is prevalent in the "straight-shot artist" and laryngeal carcinoma in the smoker.

Suppuration and hemorrhage can cause rapid changes in a neck mass and may obscure the diagnosis. A painless, enlarging mass suggests malignancy in any age group. Intermittent swelling related to eating over a period of time indicates benign salivary gland disease. Size change related to increased intrapharyngeal pressure should be sought; this suggests laryngocele. Vascular aneurysms pulsate, while fluctuation suggests a cystic structure such as a lymphangioma or branchial cyst.

Infant and Childhood Neck Masses

Lymphadenitis is by far the most common cause of childhood neck masses. A careful examination will reveal palpable nodes bilaterally. Such swellings are commonly related to an upper respiratory infection; they rarely warrant operative intervention. A diagnostic challenge presents when nodes coalesce or when drainage develops. Atypical acid-fast bacteria, dermatitis, and parasitic scalp infestations have recently become mounting considerations. Sarcoidosis and tuberculosis are less common. Viral disorders such as infectious mononucleosis and cat scratch fever are characterized by general lymphadenopathy. Dental infections and pharyngeal space infections are to be considered in toxic children. Less common causes of cervical swelling include cystic hygroma,† branchial cleft anomalies and dermoids.

Midline neck masses are almost invariably thyroglossal duct cysts. This is the rationale behind the old adage that midline masses are benign, whereas lateral masses may be malignant. Occasionally a dermoid will present in the midline.

Although a malignant process in a child's neck is very uncommon, occasionally a lymphoma will be encountered. A single, enlarging mass is indicative of sarcoma, while several adjacent, unilateral nodes suggest Hodgkin's disease.

---

*This work was supported by the National Institute of Neurological Diseases and Blindness, grants #NB04615 and #NB05349-09.

†See Test Your Word Score Page 1087.

Adult Neck Lumps

In normal adults, it is often possible to palpate cervical lymph nodes. Some may be as large as 1.0 to 1.5 cm, particularly in the subdigastric or submaxillary area.

In the adult, malignancy is the major consideration, while many swellings will prove to be benign. Lymphoma is probably the most common cause of a malignant neck mass in the young adult and usually represents a local sign of a generalized disease. Inflammatory and congenital neck masses, neurofibromas, lipomas, and carotid body tumors are less commonly encountered.

Geriatric Neck Masses

Here the overwhelming consideration is metastatic malignancy; over 80 percent of the masses will prove to be malignant. Unfortunately this adage is becoming increasingly true also for middle-aged and even young adults. Occasionally the primary lesion will be located below the clavicle, but this is the exception. Most are in the oral cavity, pharynx, or larynx, and it is incumbent upon the physician to investigate these areas thoroughly. Benign salivary gland neoplasms or duct obstruction, branchial cleft anomalies, carotid body tumors, and lymphomas will be less commonly encountered.

The Diagnostic Approach

After historical data has been tabulated, the office evaluation of a cervical mass should include an inspection of the neck from the front and palpation from behind. The sternocleidomastoid muscle is the key to the lateral neck. Neck flexion against resistance brings the muscle out, making it easier to define its relationship to an adjacent mass. Relaxing the muscle by tilting the head will allow the physician to palpate the ipsilateral neck.

The major cartilages of the neck should be delineated. The hyoid bone and the transverse processes of the cervical vertebra can be palpated. The lateral lobes of the thyroid should also be carefully palpated. Swallowing will move the thyroid gland over a gently applied palpating finger, allowing delineation of small nodules. A rough sketch of the neck serves as a graphic recording for physical findings (Figure 1).

The skin of the face and scalp should be carefully searched. A thorough ear, nose and throat examination is essential (Figure 2). Emphasis should be placed on the nasopharynx, nasal fossa and the base of the tongue. Unsuccessful mirror laryngopharyngoscopy or nasopharyngoscopy necessitates a more formal examination. Palpation is an often neglected but extremely important adjunct to the general otolaryngological examination. The palpating finger is a useful instrument for detection of small lesions in the posterior third of the tongue; oral and upper neck masses can be delineated by bimanual palpation. These procedures will often yield an otherwise occult malignancy. A funduscopic examination is particularly indicated where a melanoma is a possibility. Evaluation of the cranial nerves is equally necessary. A bruit suggests narrowing of the carotid system; a mass at the carotid bifurcation that is mobile laterally but not up and down suggests a carotid body tumor. Diagnosis and extent can be established by angiography. A chest x-ray is imperative. Routine blood studies and skin tests help define systemic and infectious disorders.

There will be occasions when a suspected primary will not be apparent despite meticulous inspection and biopsy. The importance of the general physical examination and a detailed review of systems cannot be overemphasized. Before resorting to an open biopsy, esophagoscopy, bronchoscopy and nasopharyngoscopy, sinus films, and excretory urography are indicated. Oral staining is gaining acceptance where a leukoplakia is widespread. Salivary gland and thyroid scanning is useful. Sialography, angiography, and venograms are necessary in special cases.

Biopsy of the nasopharynx is especially indicated where nodes deep to the upper sternocleidomastoid muscle or in the posterior triangle are encountered. Normal mirror nasopharyngoscopy does not eliminate the possibility of a nasopharyngeal primary neoplasm. Base of tongue and lingual tonsil biopsy may yield positive results. Diagnostic tonsillectomy has been done where initial biopsies could not document a suspected malignancy. There will be rare occasions when all investigation fails to identify a source for a neck mass. One is seldom justified in observing a neck mass in an adult. As a last resort, tissue must be obtained for pathological study.

A controversy is still current regarding the merits of needle versus open biopsy. If an open biopsy is indicated, the incision must be in a position where the local area can be excised if a larger operation is necessary. A needle biopsy site should be similarly placed and tattooed for later identification and excision. While frozen sections are increasingly reliable, there will be times when permanent sections will be required for diagnosis. An individual's experience, the mass, and the general status of the patient should be considered before securing tissue for pathological examination.

Case Report

A 59-year-old street maintenance worker was referred for diagnosis and treatment after excisional biopsy of a right neck mass, 4 x 2.5 x 1.8 cm and pathologically a poorly differentiated squamous cell carcinoma. One month prior to admission he had noted a single, painless, enlarging mass in the right lateral neck. He denied hoarseness, dysphagia, sore throat and voice change. Although he had smoked one to two packs of cigarettes daily for 40 years, this had recently been reduced. He was a heavy drinker. Following referral, an indirect mirror laryngoscopy was done. This revealed a 2-cm mass in the right pyriform sinus with normal vocal cord mobility. Biopsy of the lesion via direct laryngoscopy showed the same histology as the neck mass. The patient is now undergoing a course of preoperative irradiation to be followed by a lateral pharyngectomy and ipsilateral neck dissection.

Comment

Excision of the neck mass served only to delay definitive diagnosis and possibly contaminate the neck. The proper diagnostic approach would have been to tentatively assume (in this case correctly) that the neck mass was a metastasis and then search for the primary lesion.

Summary

The generalist, the dentist, and the specialist all have responsibility in the diagnosis of neck masses. An approach has been outlined which will avoid delays in diagnosis. Occasionally, biopsy of the neck mass is necessary, but usually the pathology of such a mass is best discovered by location of the primary tumor elsewhere in the head and neck without neck biopsy. In cases of malignancy, it is of extreme importance to preserve the integrity of metastatic neck nodes to prevent seeding of malignant cells.

Laboratory Letter

A Little on Lupus and Its Fluorescent Nucleus

Have you ever had problems establishing a diagnosis of systemic lupus? Chances are, you have. For good reasons, too. Clinically, the disease can attack any organ; tends to wax and wane; mimics related disorders, such as rheumatoid arthritis and other connective tissue diseases; and, more often than not, fails to give the textbook picture of a young woman with a butterfly rash, joint pains, sensitivity to sunlight, and leukopenia. Furthermore, even confirmed cases may have negative LE preparations; corticosteroids may suppress formation of LE cells; and many drugs can cause positive tests for lupus (Table 1).

TABLE 1

Drugs That Occasionally Give Positive LE Tests

Aminosalycylic Acid
Diphenylhydantoin
Griseofulvin
Hydralazine
Isoniazid
Mophenytoin
Methylthiouracil
Methyldopa
Oral Contraceptives
Penicillin
Phenylbutazone
Procainamide
Propylthiouracil
Streptomycin
Sulfadimethoxine
Sulfamethoxypyridazine
Tetracyclines
Trimethadione

To render precise diagnosis even tougher, tests that directly or indirectly signal the presence of lupus may cross react with serum factors generated by other diseases (Table 2).

TABLE 2

Percent of Abnormal Tests in Lupus and Related Diseases

				Connective Tissue Diseases			
Test	Adult Rheumatoid Arthritis	Juvenile Rheumatoid Arthritis	Ankylosing Spondylitis	SLE	Dermatomyositis	Periarteritis Nodosa	Scleroderma
LE cell	15%+	Rare	Negative	50-75%	Negative	Negative	Negative
Fluorescent Antinuclear antibody, titer 1:8	35%+	20%+	Negative	95-100%	10%+	10%+	70%+
Rheumatoid factor, titer 1:80	70%+	15%+	Negative	25%+	10%+	25%+	33%+

What is the fluorescent antinuclear antibody test, or FANA? In our hands, it consists of dropping fluorescein-labeled anti-human gamma globulin on an imprint of human spleen overlaid with a patient's serum. If the antibody reacts with antigen, the resulting complex fluoresces and the test is positive. We can see the nucleus glitter through an ultraviolet light microscope.

How do you interpret the result? First, FANA tests are positive in almost all patients with systemic lupus, even when LE tests are negative. Yet related diseases, especially scleroderma, can give rise to fluorescence. Still, and here lies the greatest value of FANA, a negative test virtually excludes systemic lupus. In short, all that glitters is not lupus, but lupus almost always glitters.

Drugs

Ethchlorvynol (Placidyl)

Addiction Hazard

Floyd D. Garetz, M.D.*
Minneapolis, Minnesota

It is the purpose of this paper to bring into focus what appears to the author to be the serious addiction hazard of ethchlorvynol (Placidyl). Ethchlorvynol was introduced to the North American continent in 1955 and has been used as an agent for day-time tranquilization as well as for night-time sedation. Many patients report that it produces a feeling of euphoria; most find that it relieves anxiety and is a useful sleeping medication.

As with many synthetic sedative and tranquilizing agents, ethchlorvynol was thought at first to be non-addicting. However, as with most drugs classified as minor tranquilizers as well as those called non-barbituric hypnotics, cases of addiction began to appear in the literature approximately five years after introduction of the drug. In a recent review article. Essig[1] summarizes reports of addiction to seven of the minor tranquilizers or non-barbituric hypnotics as follows: meprobamate (Equanil or Miltown); ethchlorvynol (Placidyl); glutethimide (Doriden); ethinamate (Valmid); chlordiazepoxide (Librium); diazepam (Valium); and methyprylon (Noludar).

Case Report†

The patient, a thirty-year-old male, was admitted to the hospital on September 27, 1968. On September 24 he had first revealed to his psychotherapist that he had been taking ethchlorvynol in amounts of 1500 to 2000 mgm. a day over a period of one and a half to two years but that he had stopped taking it on September 17. He reported that he had continued to take ethinamate (Valmid) during the week of September 17 to 24.

On September 26 the patient was noted to be confused at his place of work and to act as if he were hallucinating. Upon admission to the hospital on September 27, he was actively hallucinating and showed a typical picture of delirium. There were no convulsions.

Except for a hypertension of 164/100, physical and neurologic examinations were normal. Fasting blood sugar was slightly elevated to 100 mgm.% but blood urea nitrogen, cholesterol, A/G ratio, protein-bound iodine, alkaline phosphatase serology, hemogram and urinalysis were normal.

The patient was treated with thioridazine (Mellaril) and promazine (Sparine); no anticonvulsant medication was employed. He showed progressive improvement to complete clearing of consciousness on October 2 and was discharged from the hospital on October 3.

The case reported in this paper is similar to other cases reported in the literature. A review of the English literature for reports of addiction to ethchlorvynol has yielded a total of 11 cases.

The Table is a summary of certain features of 10 of the reported cases of ethchlorvynol addiction.

---

*Associate Professor, Department of Psychiatry, University of Minnesota Medical School, Minneapolis.
The author wishes to express his gratitude to S. W. Shapiro, M.D., and to S. J. Zak, M.D., for their help in preparing this paper.

Clinical Picture

On the basis of the cases presented in Table I the following points should be noted:

1. Addiction to ethchlorvynol appears in both sexes and in a wide range of ages.
2. Convulsions occur in a large proportion of cases along with a typical picture of delirium much like the delirium tremors seen in withdrawal from alcohol.
3. Clearing of symptoms occurs in five to 12 days.
4. Addiction can occur in amounts as low as 1250 mgm. per day and after only a few months of usage.
5. The cases reported were not sufficiently clear on the matter of lag period between stopping the drug and onset of symptoms. However, a lag period of from two to seven days is likely.

Treatment

A major problem in treatment is that a patient may not be suspected of being addicted to ethchlorvynol. The patient is admitted to a hospital for other purposes and, because of forced withdrawal from the drug, exhibits delirium and/or convulsions unexpectedly.

The following are guide lines in treating the withdrawal state:

1. Hospitalization is required.
2. Careful observation of food and fluid intake and output is necessary. Appropriate supportive measures should be taken when voluntary intake is not adequate.
3. Seizure precautions should be taken.
4. Phenothiazine compounds should be used to control the psychosis and agitation.

TABLE

A Summary of 10 Reported Cases of Ethchlorvynol Addiction

Case Reporter	Sex	Age	Symptoms	Symptoms Cleared	Dosage/Daily	Duration
Garza[2]	Male	40	Delirium Hallucinations Convulsions	5 days	4000 mgm.	10 years
Garza[2]	Female	26	Delirium	10 days	1000-2000 mgm.	7 years
Blumenthal[3]	Male	47	Hallucinations Convulsions	10 days	2000-2500 mgm.	9 months
Wood[4]	Female	66	Hallucinations Convulsions	12 days	2000-3000 mgm.	6 months
Hudson[5]	Female	40	Delirium Hallucinations Convulsions	10 days	1500 mgm.	Several months
Aycrigg[6]	Female	38	Delirium Hallucinations	6 days	500-2000 mgm.	1 year
Aycrigg[6]	Male	39	Delirium Hallucinations Convulsions	7 days	1000-2000 mgm.	2 years
Abuzahra[7]	Male	67	Delirium Convulsions	11 days	1250 mgm.	5 months
Cahn[8]	Female	35	Hallucinations Convulsions	?	2500 mgm.	2 years
Cahn[8]	Female	36	Convulsions	?	2000-3000 mgm.	7 months

5. Anticonvulsants should be used to reduce probability of convulsions.
6. Ethchlorvynol can be given in amounts taken by the patient before withdrawal with gradual reduction over a period of one week.
7. Phenothiazine and anticonvulsants should be continued for two weeks.

Summary and Conclusions

Ethchlorvynol (Placidyl) is a sedative, tranquilizing drug with a serious addiction hazard. Its effect of euphoria and the very narrow margin between therapeutic dosage and addicting dosage make it an even greater addiction liability than other drugs in its class.

The therapeutic use of ethchlorvynol should be restricted to hospital patients.

Patients suspected of being addicted to ethchlorvynol should be hospitalized and treated with gradual reduction of the drug as well as with phenothiazines, anticonvulsants and general supportive measures.

Medical Reporting

An all-too-common disease of early miners was silicosis. This was particularly true in the Rockies, where tunnels were forced through the mountains to get at gold deposits. Hard-rock miners at Central City, Colorado, died at an average thirty-eight years of age. Dr. H. A. Lemen of Denver described such a sufferer, whose health failed while working on a mining tunnel in Jones Mountain. He was emaciated, coughed and sweated a great deal at night, and ran a temperature of 103 degrees.

"He was expectorating daily large quantities of fluid, a specimen of which I exhibit you in this bottle," said the doctor, addressing the infant Colorado Medical Society. "He not infrequently expectorated a pint and a half to two pints of this fluid in 24 hours. His pillow case and shirt bosom were bespattered with what looked like black ink. The sentence that I am now reading was written with this fluid. The pen used has never been in ink."*

Grass

Grass is the forgiveness of nature—her constant benediction. Forests decay, harvests perish, flowers vanish, but grass is immortal.—Ingalls

Meetings

Neural-Science Seminar

A Seminar in Neurology, Neuroradiology and Neurosurgery will be held at the Minneapolis Veterans Administration Hospital on August 6, 7, and 8th. Recent advances in these fields will be reviewed. Physicians and other medical personnel are invited to attend. Cost of the Seminar will be borne by the Veterans Administration Hospital, Minneapolis, Minnesota. Rooms have been reserved for visiting participants at a minimal cost at the Sheraton Motor Inn on Highway 494. A social program as well as the lectures by outstanding faculty is being planned. You may register by writing to Dr. Milton Alter, Chief of Neurology Service, Veterans Administration Hospital, Minneapolis, Minnesota.

Southern Minnesota Medical Association Meeting

Annual convention for Southern Minnesota Medical Association in Minnesota Medicine, Saturday, September 13, 1969 at the Inn Towne Motel in Albert Lea, Minnesota.

Dermal Pathology

The University of Minnesota will present a five day course in Dermal Pathology on August 18-22, 1969. This is specifically directed to dermatologists and pathologists and will provide a very comprehensive review of the basic concepts of dermal pathology. For further information contact: Lee D. Stauffer, College of Medical Sciences, Box 193 Mayo Building, University of Minnesota, Minneapolis 55455.

Diabetes Detection

The Diabetes Detection and Education Center has been established to provide physicians in this region with a comprehensive and efficient patient and family educational program. The purpose of the Center is to serve as a resource for the physician. Patients are accepted by referral and are returned to their personal physician's care at the end of the five-day course. A complete summary of the patient's progress and acceptance of his disease is sent to each physician along with the results of all laboratory data, diet schedules, and diapeutic regimes. Five-day courses are available for patients every other week. Starting dates of these are listed below. The patient may commute from the home, community hospital, or from nearby motels or hotels. A minimal tuition is charged for the 40-hour course which includes the cost of patient's meals, laboratory determinations, insulin, etc. Patients may be enrolled by writing the Diabetes Detection and Education Center at 916 East 15th Street, Minneapolis, Minnesota 55404, or by calling 332-2446.

The burdened heart...

efore prescribing, please consult
mplete product information, a
mmary of which follows:

dications: Tension and anxiety
ates; somatic complaints which are
ncomitants of emotional factors;
ychoneurotic states manifested
tension, anxiety, apprehension,
tigue, depressive symptoms or
itation; acute agitation, tremor,
lirium tremens and hallucinosis
ie to acute alcohol withdrawal;
ljunctively in skeletal muscle
asm due to reflex spasm to local
thology, spasticity caused by
per motor neuron disorders, athe-
sis, stiff-man syndrome, convul-
ve disorders (not for sole therapy).

ntraindicated: Known hypersen-
tivity to the drug. Children under
months of age. Acute narrow angle
aucoma.

arnings: Not of value in psychotic
itients. Caution against hazardous
cupations requiring complete
ental alertness. When used ad-
nctively in convulsive disorders,
ssibility of increase in frequency
id/or severity of grand mal sei-
ires may require increased dosage
standard anticonvulsant medica-
on; abrupt withdrawal may be
sociated with temporary increase
frequency and/or severity of
izures. Advise against simulta-
eous ingestion of alcohol and other
NS depressants. Withdrawal
mptoms have occurred following
rupt discontinuance. Keep addic-
on-prone individuals under careful
irveillance because of their pre-
sposition to habituation and
ependence. In pregnancy, lactation
women of childbearing age, weigh
otential benefit against possible
azard.

recautions: If combined with other
ychotropics or anticonvulsants,
nsider carefully pharmacology of
gents employed. Usual precautions
dicated in patients severely de-
ressed, or with latent depression, or
ith suicidal tendencies. Observe
sual precautions in impaired renal
hepatic function. Limit dosage to
nallest effective amount in elderly
nd debilitated to preclude ataxia
oversedation.

de Effects: Drowsiness, confusion,
plopia, hypotension, changes in
bido, nausea, fatigue, depression,
ysarthria, jaundice, skin rash,
axia, constipation, headache, in-
ntinence, changes in salivation,
urred speech, tremor, vertigo,
rinary retention, blurred vision.
aradoxical reactions such as acute
yperexcited states, anxiety, halluci-
ations, increased muscle spasticity,
isomnia, rage, sleep disturbances,
imulation, have been reported;
ould these occur, discontinue drug.
olated reports of neutropenia,
iundice; periodic blood counts and
ver function tests advisable during
ng-term therapy.

The burdened heart,
psychic tension,
and adjunctive therapy with
Valium® (diazepam):

Artist's conception schematically showing varying ischemic ventricular muscle tissue.

To help lift psychic tension from the already burdened heart

When the cardiac patient shows signs of panic-like reactions following initial diagnosis – a daily regimen of 10-mg Valium (diazepam) tablets *t.i.d.* or *q.i.d.* can help control *severe* psychic tension, anxiety, apprehension and agitation. For *less severe* emotional stress, the 5-mg tablet usually provides the desired calming effect.

When the cardiac patient's outlook impedes convalescence – Valium, as it relieves psychic tension, can help the patient regain a realistic perspective... help him deal more rationally with convalescence by countering excessively anxious attitudes towards the future.

When the cardiac patient can't adjust emotionally to post-recovery limitations – Valium, through its prompt and pronounced calming action on psychic tension, may help avoid exacerbation or aggravation of cardiac symptoms.

On proper maintenance dosage, Valium seldom dulls the senses or interferes with functioning.

Should anxiety-induced insomnia be a problem – an *h.s.* dose added to the *t.i.d.* schedule usually helps permit a night of restful sleep.

Valium®
(diazepam)
2-mg, 5-mg and 10-mg tablets
t.i.d.* and *h.s.

JUDGE ANTIBIOTIC OINTMENTS HERE

Results on skin are final proof of any topical antibiotic's effectiveness

No in vitro test can duplicate a clinical situation on living skin. 'Neosporin' (polymyxin B — bacitracin — neomycin) Ointment has consistently proven its effectiveness in thousands of cases of bacterial skin infection. The spectra of the three antibiotics overlap in such a way as to provide bactericidal action against most pathogenic bacteria likely to be found topically. Diffusion of the antibiotics from the special petrolatum base is rapid since they are insoluble in the petrolatum, but readily soluble in tissue fluids. The Ointment is bland and nonirritating.

Caution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.
Contraindications: This product is contraindicated in those individuals who have shown hypersensitivity to any of its components.
Supplied: Tubes of 1 oz., ½ oz. with applicator tip, and ⅛ oz. with ophthalmic tip.
Complete literature available on request from Professional Services Dept. PML.

BURROUGHS WELLCOME & CO. (U.S.A.) INC., Tuckahoe, N.Y.

Dermatology

Microflora of the Skin

NORMAL HUMAN SKIN contains both in and on its surface numerous bacteria. The bacterial flora of the skin is divided into two groups, resident and transient flora. The resident flora is relatively stable in both number and type of bacteria. Most of the resident bacteria are found on or at the surface of the skin; however, studies have revealed that bacteria may be found in the deeper layers of the epidermis. The source of the resident flora has been shown to be the sebaceous gland. Bacterial counts on normal human skin are higher in areas of high sebaceous gland activity. These counts will vary from individual to individual as well as from area to area and time to time in the same individual. Studies have shown a range of 1 to 1,000,000 per cm^2.

Resident Flora

The resident flora of the skin consists, for the most part, of the following bacteria: anaerobic or microaerophilic Corynebacterium acnes, Staphylococcus epidermidis albus, aerobic diphtheroids, E. coli, proteus and various mycobacterium. The mycobacteria are acid-fast and occur mainly in the external auditory canal and the genital and axillary areas. As a rule the anaerobes outnumber the aerobes 10 to 100 times. Most of these organisms may be classified as commensals (the mutual and inconsequential association between bacteria and higher organisms). It is interesting to note that bathing frequency does not materially affect plate counts.

Recent studies have led many investigators to the conclusion that these resident bacteria play an important part in protecting the individual from more pathogenic bacteria. For example, if Staphylococcus *albus* is present on the skin, it has been shown that it is difficult for Staphylococcus *aureus* to colonize in this location. When a patient is placed on one of the "mycin" antibiotics which are known to have high skin concentrations, Staphylococcus *albus* may be destroyed, and this is then followed with invasion by the more resistant Staphylococcus *aureus*. This is further demonstrated by the fact that neomycin-resistant Staphylococcus will reproduce and thrive under neomycin dressings, *but not until* the neomycin-sensitive organisms have been destroyed. This phenomenon is less common with systemic penicillin and its derivatives, for these drugs do not achieve high skin concentrations.

Transient Flora

Bacteria comprising the *transient flora* may be of two types. First there are those organisms that are normal saprophytes from soil, water and air. These may occasionally be cultured from the surface of the skin but are not permanent residents. An example of this type is Bacillus subtillis, a gram-positive, spore-bearing aerobic saprophyte. Such organisms are important only insofar as they may be confused with some related and pathogenic species, in this case Bacillus anthracis.

The second source of transient bacterial inhabitants is the normal flora of the nasopharynx and other body orifices. These organisms are transferred to the skin by the hands. In this group may be found such organisms as Staphylococcus *aureus,* Streptococcus pyogenes hemolyticus, H. influenzae, D. pneumoniae, N. meningitidis and Klebsiella pneumoniae. Recently increasing attention has been given to another group of organisms, that of the tribe Mimeae, especially Mima polymorpha and Herellea vaginicola. Mimeae are pleomorphic, gram-negative bacilli which resemble Neisseria and may normally be found as saprophytes in a certain percentage of the population. The skin, genitalia and mucous membranes are the principle reservoirs. It is now known that serious and at times fatal infections can be caused by this species.

It is a well recognized fact that for each of the above organisms a certain percentage of the population are healthy carriers and thereby provide a reservoir for new clinical cases. It can therefore be seen that the bacterial flora of the skin may vary from relatively nonpathogenic to highly pathogenic organisms, and that this bacterial population varies greatly not only in type but in number.

It's the Law

Hospital Liable for Urethral Tear From Catheter*

A man was injured in an automobile accident, suffering fractures of the pelvis and right tibia with bladder complications. One month following the injury while the patient was being moved by two orderlies, the catheter, which the orderlies did not know about, was accidentally pulled out. The following day a superpubic cystotomy with insertion of an indwelling catheter was performed. Two weeks later, a cystoscopic examination disclosed that the patient's ureter had been torn.

In the court case, the hospital was found liable for aggravating injuries, and specifically for the urethral tear.

On Dropsies

All dropsies arising from acute diseases are bad; for they do not remove the fever, and are very painful and fatal. The most of them commence from the flanks and loins, but some from the liver; in those which derive their origin from the flanks and loins the feet swell, protracted diarrhoeas supervene, which neither remove the pains in the flanks and loins, nor soften the belly; but in dropsies which are connected with the liver there is a tickling cough, with scarcely any perceptible expectoration, and the feet swell; there are no evacuations from the bowels, unless such as are hard and forced; and there are swellings about the belly, sometimes on the one side and sometimes on the other, and these increase and diminish by turns.*

Case Reports

Cholecystocolonic Fistula

"CHOLECYSTOCOLONIC FISTULA" implies an abnormal communication between the gallbladder and the colon—two epithelial-lined surfaces. The report of a case and a review of the Mayo Clinic experience with cholecystocolonic fistulas from 1947 through 1966 follow.

Report of a Case

An 85-year-old white man entered this clinic in May 1967 complaining of anorexia and an "ill-feeling" of 1½ weeks' duration. Physical examination revealed an elderly gentleman in little apparent distress with an oral temperature of 103 F. There were a few moist rales at both lung bases and the roentgenogram of the chest revealed evidence of increased opacification of the lung bases bilaterally. Because of the bronchopneumonia he was hospitalized and treated with appropriate antibiotics after blood and sputum cultures had been obtained. He responded well. However, since the blood culture revealed *Escherichia coli,* an intensive search for the source of the septicemia was undertaken. A cholecystogram disclosed a small gallbladder containing stones and a fistula between the hepatic flexure of the colon and the gallbladder. The presence of the fistula was confirmed by barium enema (Figure 1).

The patient refused surgical treatment at this time, stating, "I'm too old for that sort of thing." He was dismissed with no special medication.

Between May and September 1967 the patient experienced occasional bouts of paroxysmal vomiting of brown material with accompanying midepigastric pain that radiated to the lower part of the abdomen bilaterally. The pain would last three to four hours and then disappear. He would sweat profusely with these attacks and thought his temperature was elevated. This syndrome had recurred every 10 to 12 days for two months prior to his rehospitalization, which was obviously required, in September 1967. His family had observed that he was jaundiced.

Physical Examination

The examination revealed a pleasant, healthy-appearing man with ruddy complexion. Blood pressure was 140 mm of mercury systolic and 90 mm diastolic, pulse rate 72 beats/min (regular), respiration 20/min, and temperature 98.4 F orally. The lungs were clear to auscultation and percussion. A grade 3 harsh systolic murmur, which extended to the right carotid artery, was heard at the aortic area. The liver edge was 1 cm below the right costal margin and the midepigastrium was slightly tender on palpation. The prostate was enlarged and indurated. The results of additional laboratory tests, including evaluation of hemoglobin, leukocyte count, differential count, urinalysis, prothrombin time, and serum protein, were all within normal limits. The serum bilirubin measured 1.4 mg/100 ml direct and 1.0 mg/100 ml indirect, the alkaline phosphatase 105 units, and the serum glutamic oxaloacetic transaminase (SGOT) 45 units.

Operative Findings

The patient submitted to laparotomy on September 11,

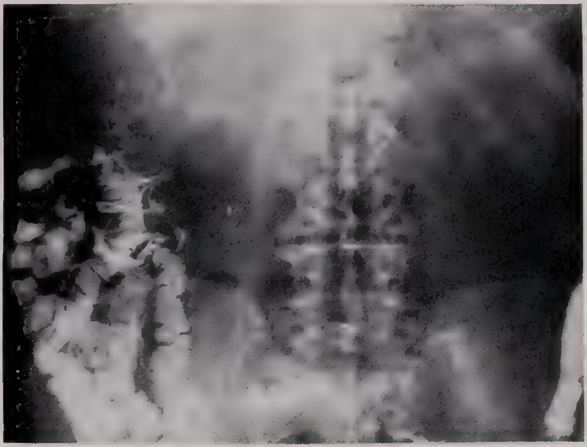

Fig. 1—Barium study of colon revealing filling of the gallbladder via a fistula.

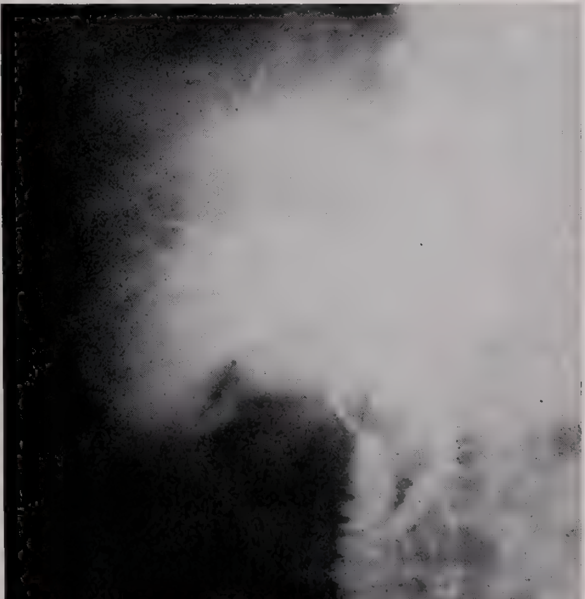

Fig. 2—Cholangiogram after operation, depicting a normal status.

1967, at which time a fibrous tract with a 5-mm lumen was found connecting the gallbladder and the hepatic flexure of the colon (after the omentum was dissected free from the area). The gallbladder contained stones, and both the cystic and the common ducts were dilated. The gallbladder with the tract was excised, the colon was closed, and the common duct was explored; sludge was removed but definite stones were not found. A cholangiogram showed the extrahepatic biliary ducts to be patent without residual obstruction. A T tube was inserted for prolonged drainage of the biliary tract. The patient did well after the operation. The only problem was nausea and vomiting, which lasted for 36 hours and then subsided spontaneously. The T tube was removed one month after operation and subsequent to repeated outpatient visits which continued to disclose an entirely normal state (Figure 2).

Comment

Incidence of the Lesion

Cholecystocolonic fistula is not a common complication of gallbladder disease. From 1947 through 1966, approximately 21,000 cholecystectomies were done at the Mayo Clinic and only 23 revealed cholecystocolonic fistulas. In 1925 Judd and Burden[1] reported a series of 153 cases of biliary-enteric fistulas, of which 26 (17%) were cholecystocolonic in type. (This incidence was slightly higher than that reported by Epperson and Walters[2] in 1953—seven of 84 (8%) biliary-enteric fistulas of cholecystocolonic type.)

This disease prevails among the elderly, the highest incidence being among persons in the eighth decade of life as the following data show: fourth decade, one; fifth decade, two; sixth decade, four; seventh decade, five; eighth decade, eight; and ninth decade, three.

Pathogenesis

The diagram of the sagittal section of the peritoneal cavity shows the proximity of the gallbladder and colon (Figure 3). Repeated attacks of cholecystitis and pericholecystitis in the presence of cholelithiasis could readily involve the hepatic flexure or the transverse colon in an inflammatory process, and necrosis with erosion of the walls of each of the viscera could result in formation of fistulas.[3,4] The element of surprise lies in the comparative rarity of this phenomenon.

Robson[4] has suggested that another mechanism of production could be formation of abscesses about the gallbladder with eventual erosion into the colon; the spontaneous drainage of such an abscess results in a fistulous tract.

It appears that cholelithiasis with or without overt cholecystitis is certainly a factor in the production of fistulas.[3] Twenty of the 23 patients in the series (1947 through 1966) had cholelithiasis, and nine had a definite history of repeated attacks of cholecystitis. In none of the cases in this series was malignancy or chronic ulcerative colitis an associated condition, although both have been reported as predisposing causes.[5,6]

Diagnosis

In spite of a thorough history, physical examination, and adequate laboratory aids, the condition can be notoriously difficult to recognize, as evidenced by the fact that in only 20% of the cases is the diagnosis made prior to operation.

Repeated attacks of fever and chills with mild to moderate jaundice and discomfort in the right upper quadrant were present in 50% of the patients.

Air in the biliary tree on x-ray examination of the abdomen is diagnostic, except for the rare case of reflux through the sphincter of Oddi. However, only two patients (9%) in this series had air in the biliary tree. Occasionally a radiopaque gallstone will be visible in the region of the sigmoid colon. A barium enema is useful, sometimes outlining the gallbladder and biliary tree as well as the fistula.

Cholecystography is usually not rewarding, since the majority of cases exhibit only a non-

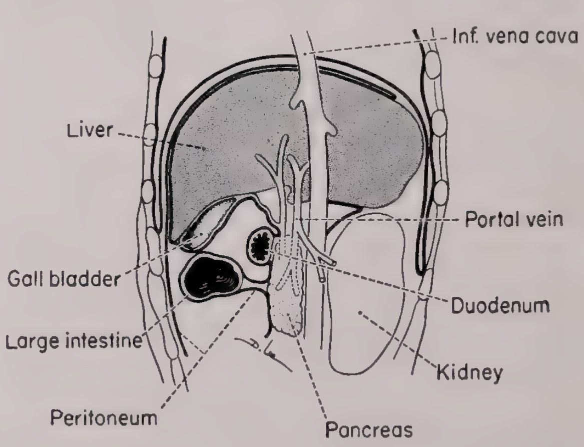

Fig. 3—Sagittal section of peritoneal cavity showing proximity of gallbladder to colon.

functioning gallbladder. Ten of the 23 patients were found to have a nonfunctioning gallbladder at cholecystography.

Complications

Ascending cholangitis with septicemia and jaundice is a frequent problem prior to surgical treatment. In this series 45% of the patients had a history of repeated attacks of fever, chills, and jaundice. Diarrhea and malabsorption can be troublesome and may result in loss of weight and vitamin deficiency.[7,8] A number of investigators have postulated that this may be caused by the presence of highly irritative bile salts in the colon. A hemorrhagic diathesis is sometimes present. In numerous cases fistulas presenting as massive gastrointestinal hemorrhage probably secondary to vitamin K deficiency have been reported.[9] Since the majority of the patients are elderly with other concomitant diseases, the surgical repair is not accomplished without a degree of morbidity and mortality. One patient in this series died one week after operation in congestive heart failure.

Treatment

Preventive

The most important single factor resulting in a decreasing incidence appears to be prompt removal of the diseased gallbladder.

Definitive

Cholecystectomy with closure of the fistulous opening into the colon, after adequate preoperative preparation of the patient, cures the disease. Present-day adjuncts, especially specific antibiotics, are extremely helpful.

Summary

Cholecystocolonic fistula is seen most commonly after repeated attacks of cholecystitis with cholelithiasis. It can be complicated by periodic attacks of ascending cholangitis, a hemorrhagic diathesis, and diarrhea and malabsorption with loss of weight. The preoperative diagnosis depends on a complete history, physical examination, and adequate laboratory aids, especially x-ray studies. The treatment is definitive: cholecystectomy with closure of the fistula after adequate preparation of the patient.

Fine

Two psychiatrists met on the street one day, and one said to the other, "You're fine. How am I?"

But before you prescribe Pertofrane, please see the full prescribing information and especially note Contraindications, Precautions, Warning, Adverse Reactions and Dosage. A brief summary of that information is included here.

Pertofrane® desipramine hydrochloride

Indications: For relief of depression.
Contraindications: Do not use drugs of the M.A.O.I. class with Pertofrane. Hyperpyretic crises or severe convulsive seizures may occur; potentiation of adverse effects can be serious or even fatal. When substituting this drug in patients receiving an M.A.O.I., allow an interval of at least 7 days. Initial dosage in such patients should be low and increases should be gradual and cautiously prescribed.
Warning: Activation of psychosis may occasionally be observed in schizophrenic patients. Do not use in patients under 12 years old, and do not use in women who are or may become pregnant unless the clinical situation warrants the potential risk.
Precautions: Careful supervision and protective measures for potentially suicidal patients are necessary. Discontinuation of therapy or adjunctive use of a sedative or tranquilizer may be necessary in the presence of increased anxiety or agitation, hypomania or manic excitement. However, phenothiazines may aggravate the condition. Atropine-like effects may be more pronounced (e.g. paralytic ileus) in susceptible patients and in those receiving anticholinergic drugs (including antiparkinsonism agents). Carefully observe patients with increased intraocular pressure. Prescribe cautiously in hyperthyroid patients and in those receiving thyroid medications. Cardiovascular complications (myocardial infarction and arrhythmias) are potential risks since they have occasionally occurred with imipramine, the parent compound. Desipramine may block the pharmacologic activity of guanethidine and related adrenergic neuron-blocking agents. Hypertensive episodes have been observed during surgery in patients on desipramine therapy. Before prescribing the drug, the physician should be thoroughly familiar with prescribing information, with the literature, with all adverse reactions, with the diagnosis and management of depression, and with the relative merits of all measures for treating the condition.
Adverse Reactions: Dry mouth, constipation, disturbed visual accommodation, anorexia, perspiration, insomnia, drowsiness, dizziness, headache, nausea, epigastric distress, and skin rash (including photosensitization) may appear. Since orthostatic hypotension has occurred, carefully observe patients requiring concomitant vasodilating therapy, particularly during the initial phases. Other adverse reactions include tachycardia, changes in EEG patterns, tremor, falling, mild extrapyramidal activity, neuromuscular incoordination, epileptiform seizures. A confusional state (with such symptoms as hallucinations and disorientation) occurs occasionally and may require reduced dosage or discontinuance of therapy. Rarely, transient eosinophilia, slight elevation in transaminase levels, transient jaundice, or liver damage have occurred. If abnormalities occur in liver function tests, discontinue drug and investigate. Occasional hormonal effects, particularly decreased libido or impotence and instances of gynecomastia, galactorrhea and female breast enlargement have been observed. Urinary frequency or retention may occur. The drug should be discontinued if agranulocytosis, bone marrow depression, jaundice, thrombocytopenia, or purpura occur.
Dosage: 25 to 50 mg. t.i.d. The maximum daily dose is 200 mg. Continue maintenance dosage for at least 2 months after obtaining satisfactory response. Generally, elderly and adolescent patients should be given low doses.
Availability: Pink capsules of 25 mg. in bottles of 100 and 1000. (B) 46-530-E

What makes a

A man?
Another woman?
Three kids?
No kids at all?
Wrinkles?
You name it.

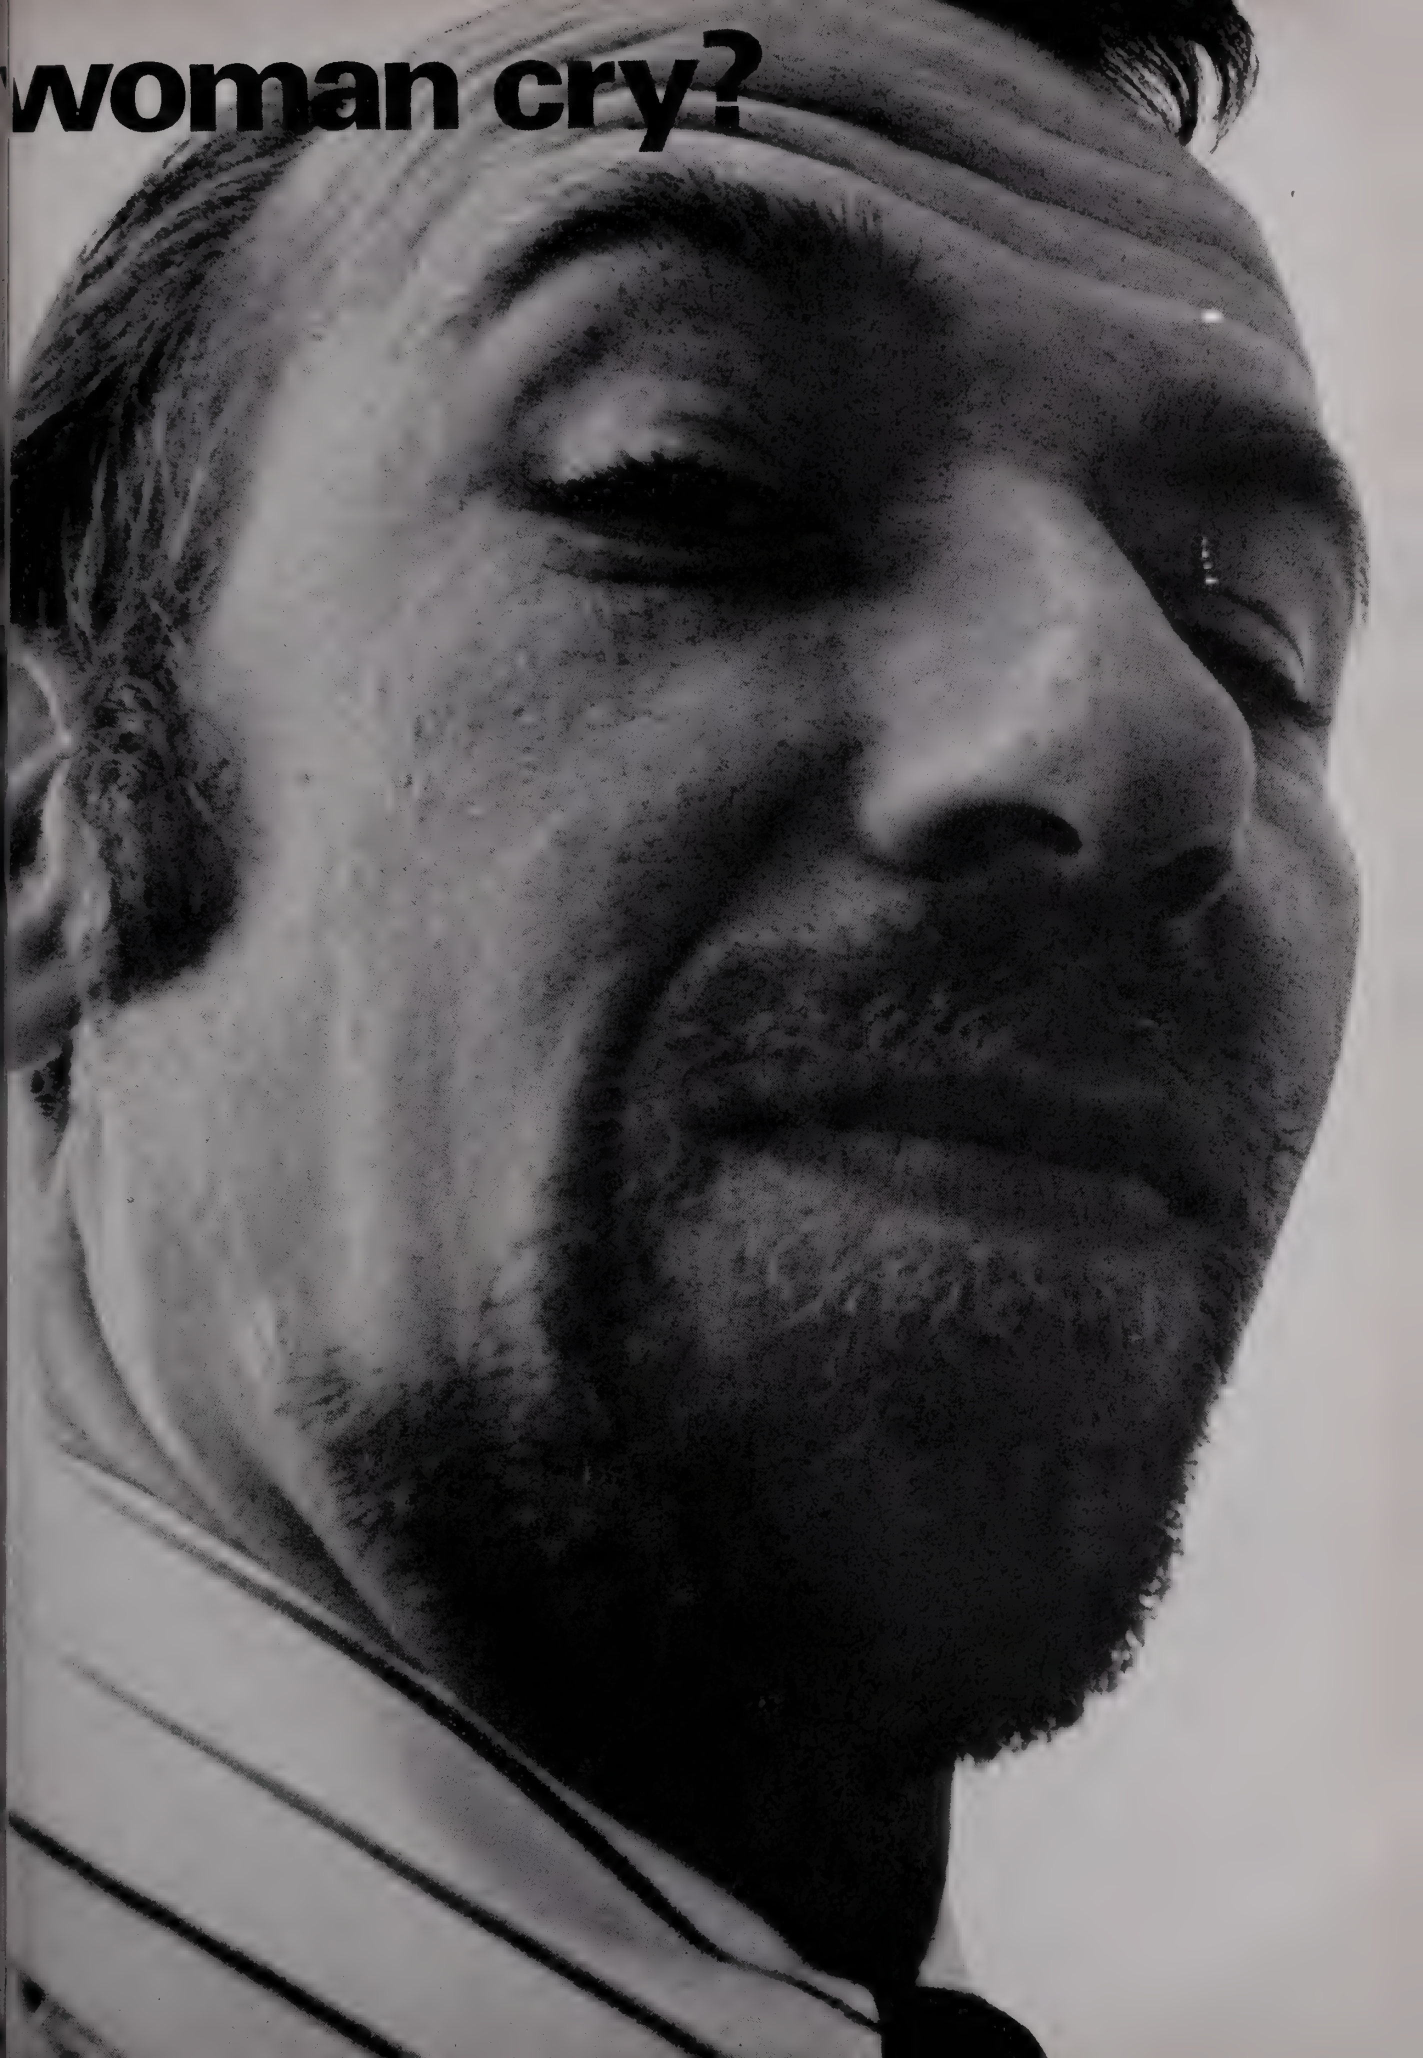
Is she truly depressed?

Is that why she lets go
in your office?

You comfort her.
Talk to her.
And, if she is depressed,
consider Pertofrane.
Because
in 3 to 5 days
she can often begin
to cope,
work,
maybe play,
even enjoy.

Pertofrane®
desipramine hydrochloride
In depression...
when words are not enoug

woman cry?



For elderly patients
in need of a mild tranquilizer
consider **Tybatran**®
brand of tybamate

(When you consult
the Prescribing Information
you may agree
it makes good sense)

PRESCRIBING INFORMATION

Indications: Tybatran (tybamate) has afforded symptomatic improvement in a variety of psychoneurotic disorders, especially in the treatment of the anxiety and tension components of psychoneuroses. Anxiety states manifested somatically have responded to Tybatran (tybamate).

Tybatran (tybamate) has been useful in the control of agitation in the aged and in the alleviation of some of the adverse emotional accompaniments of senility.

Tybatran (tybamate) has been used with benefit in the treatment of depressive symptoms associated with anxiety and other symptoms of psychoneuroses. However, it is not indicated for primary treatment of depressive states. It is not an antipsychotic agent, although it has been used as adjunctive therapy in some psychotic patients.

Dosage: One 350 mg. capsule, 3 times daily and two at bedtime is suggested as the adult starting dose. Adjust to suit individual requirements. Daily doses above 3000 mg. are not recommended.

Contraindications: Known hypersensitivity to tybamate. Since no studies have been done with this drug in human pregnancy, it should not be used in pregnancy unless the potential benefit outweighs the risk.

Warnings: Administer cautiously to patients receiving phenothiazines or other CNS depressants or having history of convulsive seizures (See Adverse Reactions). Consider possibility of additive actions with alcohol or other psychotropic agents, particularly phenothiazines or MAO inhibitors.

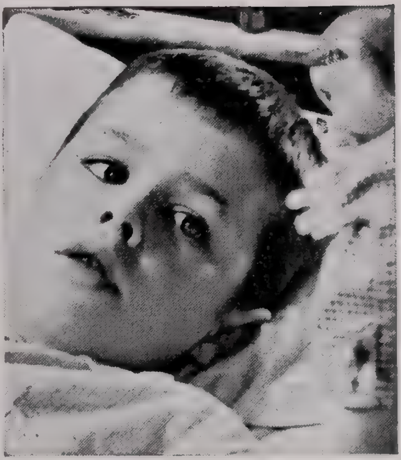
Precautions: Avoid abrupt withdrawal after prolonged use, although withdrawal symptoms have not been reported to date. Exercise caution in addiction-prone individuals. If symptoms of hypersensitivity occur, discontinue at once and initiate appropriate symptomatic treatment. Avoid activities requiring optimal mental alertness if drowsiness or vertigo are present. As with any new drug, use cautiously in patients with history of drug allergies, blood dyscrasias, and hepatic or renal disease; periodic measurements of hepatic, hematopoietic and renal function should accompany prolonged and/or high doses.

Adverse Reactions: Most frequent reactions, rarely requiring discontinuation of tybamate, include drowsiness, dizziness, nausea, insomnia, and euphoria. There have been a few reports of skin rash, urticaria, and pruritus. Rare side effects include hyperactivity, fidgetiness, flushing, and tachycardia, suggesting excessive stimulation; also ataxia, unsteadiness, confusion, feeling of unreality, "panic reaction," fatigue, headache, paresthesias, vertigo, gastrointestinal disturbances, glossitis, and dry mouth. Grand mal or petit mal seizures have been reported in a few hospitalized psychotic patients receiving tybamate (up to 6000 mg. daily) together with phenothiazines and other psychotropic agents, but not with tybamate alone. Consider the possibility of rare, serious adverse reactions such as may occur with the related drug, meprobamate. If excessive amounts are ingested, gastric lavage and symptomatic therapy, including central stimulants as necessary, are recommended. Before prescribing, consult package circular.

Supply: Tybatran (tybamate) is available in green, sealed capsules of three strengths: 350 mg., 250 mg., and 125 mg. Each strength is supplied in bottles of 100 and 500.

A. H. Robins Company, Richmond, Va. 23220

A·H·ROBINS



Save him from RHEUMATIC FEVER

Here are two ways:

1. If your child has a bad sore throat, don't wait – it might be "strep." Call your doctor. Treatment of "strep" infections usually can prevent rheumatic fever and the heart damage it sometimes causes.

2. Give to your Heart Fund. Your Heart Fund dollars support research and community service programs which can wipe out rheumatic fever and save thousands of young lives.

GIVE ...
so more will live

TEN MAN MULTISPECIALTY group needs an ophthalmologist and another pediatrician. New clinic building, complete laboratory and x-ray facilities. 180 bed modern hospital across street from clinic. Early share-holder status. Salary open. Write or call the Lenont-Peterson Clinic, Ltd., C. A. Tietz, M.D., area code 218, 741-4292, Virginia, Minnesota 55792.

WANTED: Young physician for association leading to partnership with four well established General Practitioners in fast growing suburb of St. Paul. Excellent clinic facilities in nearly new, partnership owned, well equipped, medical center building. Write: MINNESOTA MEDICINE-421, 375 Jackson, St. Paul 55101.

WANTED: G.P. to join clinic serving population area of 12,000. City has new hospital, new clinic building, two nursing homes, new Jr-Sr high school, new swimming pool, rich farming area. Fishing and hunting nearby; metropolitan city close by. Salary open and partnership if interested. Write: MINNESOTA MEDICINE-423, 375 Jackson, St. Paul 55101.

VACATION PLANS: Family activities: Water skiing, canoeing, fishing, tennis, boating, beach, sauna, picnics. Supervised children's games, beach fun, baby sitters. American plan with three meals a day. Family rates. Write for folder and rates to Burntside Lodge, S.R. 1, Box 372, Ely, Minnesota, Phone 218—365-3894.

INTERNIST, PEDIATRICIAN, ORTHOPEDIST, GENERAL PRACTITIONER, GENERAL SURGEON to join nineteen-man Wisconsin group located in college community of 40,000 with excellent hospital facilities. For further information contact D. R. Griffith, M.D., Midelfort Clinic, Eau Claire, Wisconsin.

GENERAL PRACTITIONER to join two-man group, ages 35 and 38, St. Paul suburb, near lake. Excellent hospital affiliation. Estimated $30,000 plus first year, equal partner second year if mutually agreeable. Write MINNESOTA MEDICINE-439, 375 Jackson, St. Paul 55101.

YOUNG EXPERIENCED GP with family and excellent background desires to relocate. Will consider any location if financially attractive. Write: Minnesota Medicine-437, 375 Jackson, St. Paul, Minnesota 55101.

STUDENT HEALTH SERVICE: Doctor to develop health service for college of 5,000 located in metropolitan community. Regular hours, four weeks vacation, major holidays. Contact Dr. Robert MacLeod, Dean of Student Personnel Services, Moorhead State College, Moorhead, Minnesota 56560.

ST. MARY'S HOSPITAL is seeking an experienced physician to supervise the hospital's Emergency Room program. This is a full time position carrying satisfactory salary and perquisites including retirement program. Position requires attendance in the Emergency Room five days a week, administration and supervision of residents who man the facility evenings, nights and weekends. Write John J. Regan, M.D., Chief of Staff, St. Mary's Hospital, 2414 South Seventh Street, Minneapolis, Minnesota 55406.

GENERAL PRACTITIONER wanted for 4 man GP group with board surgeon associated with community sponsored prepayment plan in NE Minnesota area of 14,000 located on Lake Superior near Duluth; accredited hospital with radiologist, pathologist and internist services next door to modern clinic; good schools with swimming pool and indoor ice arena, golf, hunting, fishing; liberal salary, $20,000-$25,000 first year; full partnership 6 months; equitable rotating call schedule. No age limit. Write Medical Director, Community Clinic, Two Harbors, Minnesota.

PSYCHIATRIC RESIDENCIES: We offer nothing but excellent psychiatric training in a stimulating, well organized program located in a culturally advantaged community. Approved psychiatric training. Traverse City State Hospital, Michigan Department of Mental Health. Three and five year programs. Salary, 3 year program: $10,669; $11,191; $12,131. 5 year program: $12,152; $14,031; $16,328. $21,944; $23,093. NIMH-GP stipends available. Located in Michigan's serene, scenic recreation area on Grand Traverse Bay. Contact Dr. Paul E. Kauffman, Director of Training, Traverse City State Hospital, Traverse City, Michigan 49684. An equal opportunity employer.

WANTED G.P. to take over for retiring M.D. In present location for 53 years. Good business town, good churches, schools and new hospital. Not far from St. Cloud and Twin Cities. Write: MINNESOTA MEDICINE-435, 375 Jackson St., St. Paul 55101.

640 ACRES, 360 tillable, fertile sandy loam soil, buyer receives ⅓ of 1969 crop. $20,000.00. Johnson Realty, Hallock, Minnesota, Phone: 843-2103.

GP AND OB GYN wanted to join two GPs, surgeon, and internist in suburban group. Excellent nearby hospital. Salary first year, then partnership. Write MINNESOTA MEDICINE-436, 375 Jackson, St. Paul 55101.

WANTED: General Practitioner or Internist, to join four man group in St. Paul. Partnership possible in one year. Dr. V. L. Sommerdorf, 1239 Payne Avenue, St. Paul, Minnesota 55101.

GENERAL PRACTITIONER wanted to join well-established practitioner. New clinic building—90 miles east of St. Paul—city of 14,000. Early partnership with full hospital facilities. Ideal location. L. W. Picotte, M.D., Chippewa Falls, Wisconsin.

PRACTICE OPENING in busy, booming, Bloomington. Sports and culture opportunities; good schools, etc. Join three young G.P.'s rotating call—new ideas in medical care—Contact Richard K. Simmons, M.D., 8040 Penn Avenue So. 612—888-9211.

MEDICAL OFFICES FOR RENT University Avenue St. Paul. Entire upper floor of building used for clinic for last 25 years. Considerable equipment and furniture available. Large practice which was attended thru May of 1968, is unattended due to doctors death. Contact Dwain H. Legler, 200 St. Paul Federal Savings & Loan Bldg., 8th & Cedar Streets, St. Paul 55101. Phone 222-4426.

Book Reviews

Books are ships which pass through the vast seas of time.—Bacon

ATLAS OF PRECAUTIONARY MEASURES IN GENERAL SURGERY by Ivan B. Baronofsky; C. V. Mosby Co. 1968. $23.50.

Dr. Baronofsky has prepared an Atlas of "Defensive Surgery" in which he aims to point out surgical landmarks that may prevent certain serious complications if the operator can keep them carefully in mind during the procedure.

The introduction is written by Dr. Baronofsky's teacher, Professor Owen H. Wangensteen. The Professor obviously favors this approach for the surgeon confronted with the responsibility of familiarizing himself with certain details of an operation before undertaking it, and thus by "pre-visioning obviate the disasters of complications."

This Atlas contains 275 pages covering 25 procedures. The description is concise and the artistry of the illustrator, Daisy Stilwell, is superb. The various procedures described cover a rather broad area of general surgery, including some less common operations of particular interest to the author.

The author will no doubt receive a deluge of "why didn't you do — — — so-and-so, or why was this or that item not included?" However, a very broad area of experience has been employed. The section on gastric surgery is quite complete. The experience in this area has been particularly broad since, if this reviewer's memory serves correctly, the mere start of Dr. Baronofsky's experience began with 54 subtotal gastrectomies done during his chief residency.

Some doubts, however, might be raised by the author's praise of catheter duodenostomy, particularly since that particular method requires caution and perhaps in addition, an outline of the surgical tricks required to avoid the difficulties produced by the catheter itself. On page 74 a drawing of the mesocolon sutured to the jejunal loop is presented as an example of a *wrong* method; but it is identified as wrong only in the text. An unmistakable caption "WRONG" should be used, because a rapid reader might very well look at the drawings and by not carefully reading the text conclude that this is one of the methods to employ, whereas the illustration is used only as an example of error. The author's caution regarding the absolute necessity for operative cholangiography introducing dye into the duodenum before closing the abdomen might well be debated by those who feel that they can diagnose spasm by the character of the ending of the dye, even though it does not enter the duodenum.

This reviewer suggests that this Atlas of General Surgical Procedures is a very useful book for the resident and at times might be helpful to the surgeon who wishes to review an unfamiliar area.

J. H. Strickler, M.D.
Minneapolis, Minnesota

COMPREHENSIVE REVIEW FOR MEDICAL TECHNOLOGISTS, edited by Francis E. Dolan, Ph.D., Professor of Anatomy and Physiology, and Chairman, Department of Medical Technology and Biology, University of Bridgeport, Connecticut. C. V. Mosby Company 1968, pp. 155. $6.95.

The purpose of this multiauthored booklet is to aid the preclinical trainee in medical technology preparing for the National Registry Examination and the medical technologist who has been away from the field for many years. These two objectives are accomplished by compiling 603 questions and answers covering ten disciplines in medical technology: clinical chemistry, pretransfusion and blood bank, serology and immunology, bacteriology, hematology, parasitology, mycology, histology including cytology, urinalysis and clinical microscopy, and miscellaneous techniques. The latter includes 35 items, among them microscope, stains, reagents, anticoagulants, sterilization, etymology, mathematics. Though anatomy and physiology are not listed as disciplines, Dr. Dolan has devoted 30 pages and 157 questions and answers to these subjects. According to medical technologists I have consulted, these fields are not part of the National Registry Examination.

In Chapter 9, "Hematology," the question "What are Cabot's ring bodies?" is answered "—are seen in anemias, possibly representing nucleic acid not incorporated into hemoglobin." This leaves the student with the impression that Cabot rings occur in all anemias. This is not the case. If there is tangible histochemical evidence that nucleic acids, hemoglobin and Cabot rings are related, it is not common knowledge, and the original source for this answer should have been cited. Many other debatable answers and lack of literature references do not encourage me to recommend this booklet as an authoritative work to medical technologists, but I am inclined to approve it as an aid to the preclinical trainee preparing for the National Registry Examination.

The C. V. Mosby and Company has done a fine job selecting the printing type, presenting the text in a two column form, and binding the booklet.

A little Hygroton
chlorthalidone

HY-6674

can work a long diuretic day

ll the way from one daily tablet to the next
help control edema and hypertension

s prolonged action usually provides smooth, sustained diuretic fectiveness; real one-a-day dosage, right from the start; convenience nd economy.

ygroton, chlorthalidone, can cause side effects. And it's contra-dicated in hypersensitivity to the drug and severe renal and epatic diseases.

heck the prescribing information. It's summarized on the next page.

Geigy

A little Hygroton® can work a long diuretic day

chlorthalidone

Indications: Hypertension and many types of edema involving retention of salt and water.
Contraindications: Hypersensitivity and most cases of severe renal or hepatic diseases.
Warning: With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has been required frequently and deaths have occurred. Discontinue enteric-coated potassium supplements immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur.
Use with caution in pregnant women and nursing mothers since the drug may cross the placental barrier and appear in cord blood and since thiazides may appear in breast milk. The drug may result in fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. When used in women of childbearing age, balance benefits of drug against possible hazards to fetus.
Precautions: Antihypertensive therapy with this drug should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents, other potent antihypertensive drugs or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. Because of the possibility of progression of renal damage, periodic determination of the BUN is indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated.
Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, the drug should be discontinued and potassium supplements given, provided the patient does not have marked oliguria.
Take special care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.
Adverse Reactions: Nausea, gastric irritation, vomiting, anorexia, constipation and cramping, dizziness, weakness, restlessness, hyperglycemia, glycosuria, hyperuricemia, headache, muscle cramps, orthostatic hypotension, which may be potentiated when chlorthalidone is combined with barbiturates, narcotics or alcohol, aplastic anemia, leukopenia, thrombocytopenia, agranulocytosis, impotence, dysuria, transient myopia, skin rashes, urticaria, purpura, necrotizing angiitis, acute gout, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Other reactions reported with this class of compounds include: jaundice, xanthopsia, paresthesia, and photosensitization.
Average Dosage: 50 or 100 mg. with breakfast daily or 100 mg. every other day.
Availability: White, single-scored tablets of 100 mg. and aqua tablets of 50 mg., in bottles of 100 and 1000.

Trichinosis Outbreak in Minnesota and Iowa*

Associated with Consumption of Summer Sausage

LESLIE P. WILLIAMS, JR., D.V.M.†
Fort Collins, Colorado

C. B. NELSON, M.D.‡
Minneapolis, Minnesota

CARL L. ZYMET, D.V.M.#
Ossining, New York

In the five-year period 1960 through 1964, an average of 233 (range 306-160) trichinosis cases per year have been reported in the United States, with an average mortality of 3.4 deaths per year. During the same time period, six cases were reported in Minnesota and 33 in Iowa.[1,2,3,4,5] These usually occurred as sporadic cases, and the source of the infection was difficult to ascertain; however, when several cases were related in time and place, as indicated by a laboratory receiving a number of sera with requests for a trichinosis test, or through epidemiological follow-up at the suggestion of a practicing physician, the source was often determined.[6,7,8,9] Roselle et al. tested a sample of bear meat, and trichinella larvae were demonstrated. In the other reports, no portions of the suspect meat could be found, and epidemiological evidence was relied upon to demonstrate that commercially ground hamburger[7,8] and ground ham[9] were the most probable vehicles of infection.

This is a report of an epidemic involving 44 Minnesota and Iowa residents (37 cases and seven suspected cases) living in the vicinity of a combination butcher-shop lockerplant near the border of these two states. The most probable source of this outbreak was smoked summer sausage that was produced by this plant and consumed around Thanksgiving, 1964. In addition to being a large outbreak, one death was associated with it. The persons involved were designated as cases, or suspect cases, on the basis of clinical histories, eosinophil counts, and the results of one of two serologic tests for trichinosis. In Minnesota the Bentonite flocculation test (BFT)[10] is used*; Iowa uses the Sussenguth-Kline.[11]

†At the time of this investigation, Dr. Williams was Epidemic Intelligence Service Officer (NCDC) assigned to the Minnesota Department of Health. He is presently an Associate Professor, Department of Microbiology, College of Veterinary Medicine, Colorado State University, Ft. Collins, Colorado.

‡Chief, Section of Acute Communicable Disease, Division of Disease Prevention and Control, Minnesota Department of Health.

#At the time of these investigations, Dr. Zymet was Epidemic Intelligence Service Officer (NCDC) assigned to the Iowa State Department of Health. He is presently in the private practice of Veterinary Medicine, Ossining, New York.

The Epidemic

On January 4, 1965, a physician called the Minnesota Department of Health to report a possible trichinosis outbreak beginning on December 13, 1964. Approximately 15 persons experienced symptoms compatible with this disease and had eosinophil percentages ranging from 12% to 54%. Three patients required hospitalization, and one of these died on January 1. The physician at first suspected a contagious viral illness and, in order to confirm this diagnosis, requested a white blood count and differential counts on seven of the eight nurses, the laboratory technician in the local hospital, and herself ten days after the three cases had been hospitalized, since these individuals might have been exposed. All had counts within normal limits. None of them experienced any illness. These findings reinforced the doctor's second diagnosis, trichinosis.

The Initial Cases

A preliminary investigation revealed twenty-four possible cases ranging in age from four to 65 years. The most common symptoms were myalgia, intermittent fever, malaise, periorbital or facial edema, vomiting, diarrhea, conjunctivitis, and abdominal cramps. One of these suspect cases was a butcher in Minnesota who operated a combination locker-plant and butcher-shop in a very small town near

*This test is performed at the National Communicable Disease Center.

the Minnesota, Iowa, Wisconsin borders. About a week later two of us (LPW and CBN) visited the area, collected blood specimens for the Bentonite flocculation test[10] and eosinophil counts, and obtained further clinical data. When the Bentonite flocculation test results were received from the National Communicable Disease Center, Atlanta, Georgia, the two neighboring states were notified of the outbreak. No cases in Wisconsin were connected to this outbreak. A check of the records of the State Hygienic Laboratory of the Iowa State Department of Health uncovered one case in Northern Iowa, where the attending physician had requested a Sussenguth-Kline[11] test for trichinosis on January 6. The result was a 1:64 titer. Subsequent investigations brought six more cases to the attention of Iowa authorities.

Two months later, we again contacted the cases and collected blood specimens from them. The names of an additional twenty possible cases were obtained and most of these persons were interviewed and a blood specimen was collected. Fourteen were determined to be cases on the basis of clinical history and laboratory findings. The list of cases that were initially diagnosed by Bentonite flocculation test or by the Bentonite flocculation and Sussenguth-Kline tests are shown in Table 1. A Bentonite flocculation test titer of 1:10 or higher is considered indicative of current infection. A Sussenguth-Kline titer of 1:4 or higher is considered positive by Iowa health officials. Where three eosinophil percentages are shown, the first one listed was derived from the differential counts requested by the private physician prior to our investigation of the outbreak. Those cases intially diagnosed by the Iowa State Hygienic Laboratory, using the Sussenguth-Kline test, are shown in Table 2. The data of an additional seven persons having symptoms compatible with the disease but no supporting laboratory findings are shown in Table 3. The dates of onset of clinical symptoms are shown in Figure.

The Common Vehicle

The only common meat food items consumed by the majority of the persons between the last week of November and the second week of December was summer sausage from Case 8A's locker plant. Twenty-seven persons had either purchased or consumed summer sausage during this period, or had definite knowledge that they had eaten it at a party; thirteen stated that they thought they had eaten it at a party or that they

Figure

ate it frequently and thought they had bought some in early December. The experience in two of the cases was of special interest. The resident of Illinois, 4C, was in the outbreak area only from November 16 to November 23, 1964. She ate summer sausage near the end of her visit. Seventeen A was clearing timber for 16A on December 5, 1964. During the work day, 16A shared his lunch of summer sausage sandwiches with him. This was the only time 17A ate this meat during November and December to the best of his wife's knowledge. Sixteen A stated that he bought summer sausage only from 8A's locker.

The patient, 19B, who died, was a 52-year-old farmer. He was seen by his physician on December 18, with a history of illness of one week, characterized by upper abdominal pain, vomiting, backache, malaise, and generalized muscle pain. His eosinophil percentages while he was in the local hospital, were 28, 25, and 17%. He was then transferred to a Wisconsin hospital where his differential counts were 13 and 17% eosinophils and his absolute blood eosinophil count was elevated to 821/cu. mm. He experienced severe diaphragmatic pain and spiking fever. Trichinella skin and latex tests were negative. Agglutination tests for brucellosis, typhoid, paratyphoid and proteus were negative. The L.E. cell test was negative. No ova or parasites were found in his feces. Skin tests for histoplasmosis, coccidiomycosis, and North American blastomycosis were all negative. His blood culture was sterile. He died unexpectedly on January 1. Trypsin digestion was done on several muscle specimens but no larvae were recovered. The pathologist's report states: "Although these sections present a characteristic pattern of lesions compatible with trichiniasis in the skeletal and cardiac musculature, we have been unable in several hundred sections examined to identify the larvae and encysted form of the parasite. . . . We have labelled this case one of presumed trichiniasis" (personal communication, Dietz,[12] 1965).

Preparation of the Sausage

Eight A stated that pork butts used in the manufacture of summer sausage were purchased only from United States Department of Agriculture-inspected meat plants. The butts were boned, boxed, and held at −5°F for 30 days as recommended by the Minnesota State Department of Agriculture to kill trichina larvae. The meat was then thawed, ground and mixed with United States Department of Agriculture-inspected beef, put in natural beef casing and smoked for three days at 110°F. His total sales were about 600 pounds a month (wholesale and retail). Six B bought summer sausage wholesale and sold it to several small Iowa food markets in the area (an illegal act in interstate commerce since it was not produced under United States Department of Agriculture supervision). Since 8A seemed very conscientious about complying with the state recommendations, we can only speculate as to the possible source of the outbreak. It seems most likely that either a grinder was left uncleaned after being used for sausage making or that an unfrozen pork butt was used in the making of summer sausage by mistake. In all

probability, only one lot of 200 pounds was infested with larvae. However, none of the suspect sausage could be recovered for examination.

Discussion

A previous series[13] reviewed the occurrence of trichinosis in the State of Minnesota from 1913 to 1947 and reported on 37 clinical cases in a small village. The similarities between the 1947 outbreak and the present one included similar symptom complexes, some very high eosinophil counts, patients of predominantly Central European stock, and a history of having consumed smoked summer (country) sausage. It was also noted in this report that pork had been involved in all cases in Minnesota where a source of trichinosis had been suspected or found.[13]

The usual incubation period is five days but may be as short as 18 hours or as long as 28 days.[13] During this stage gastroenteritis may occur;[13,14] one half of our patients experienced one or more symptoms of gastroenteritis. The next stage is that of muscle invasion and larval migration when the symptoms usually associated with this disease occur.[14] Eosinophilia occurs in the second week, usually peaks in the third week, and gradually decreases over several months. Myocarditis is the most serious complication of trichinosis and is the usual cause of death. Approximately 26% of the patients with myocarditis will show electrocardiographic changes, but clinical evidence of these changes is usually absent. Larvae invade the myocardium but do not encyst there.[15,16] No electrocardiographic changes were reported from 19B's tracing made eleven days after the onset of his symptoms.[17]

Twenty-seven serum specimens collected on March 2, 1965, had both the Bentonite flocculation test and the Sussenguth-Kline test completed. Seven of these (26%) were not positive by the Bentonite flocculation test (titers less than 1:10) but were positive by the Sussenguth-Kline test (titers greater than 1:4). These data support the findings of Norman and Kagan (1963) from several comparison studies of these and other diagnostic tests for trichinosis. Maynard and Kagan stated that the Bentonite flocculation test has the most value in acute stages of infection and that the Sussenguth-Kline test is of particular worth in detecting chronic infections. They believe that the Bentonite flocculation test is a most valuable test due to excellent specificity and sensitivity that will detect individuals with antibody from a current infection.[14] There is agreement between these statements and the recent research by National Communicable Disease Center workers in evaluating trichinosis tests to detect swine infections. The Sussenguth-Kline test was one of their tests of choice because it becomes positive early in experimental disease and continues positive for a long time.

The preventive measures against trichinosis set forth by the American Public Health Association are briefly:[20]

1. Adequate processing of pork products and separate grinders for pork where processing requires grinding of meats from various animals.
2. Cooking of garbage and offal fed to swine.
3. Education of the public to cook all fresh pork or pork products for a time and at a temperature such that all parts of the meat reach at least 65.5°C (150°F) if not processed under United States Department of Agriculture regulation.
4. Freezing of pork or pork products to −27°C (−16°F) (central portion temperature) for 36 hours.

The U.S. Department of Agriculture regulations state that meat products, not customarily well cooked in the home, shall be heated to an internal temperature of 137°F or higher, or frozen at 5°F for 20 days, −10°F for 10 days, or −20°F for 6 days.[21] Eight A's treatment of the pork used in his summer sausage was adequate and complied with State recommendation; however, his treatment was not terminal or applied to the completed product. The United States Department of Agriculture requirements offer a greater protection for the consumer by treating the finished product, thus insuring against such an error as was probably responsible for this outbreak.

Summary

A trichinosis outbreak involving Minnesota and Iowa residents was investigated during the first quarter of 1965. Thirty-seven cases were identified. Diagnosis was based on clinical symptoms, food histories, eosinophil percentages, and the results of the Bentonite flocculation test and/or the Sussenguth-Kline test. One person associated with the outbreak died of presumed trichinosis. The epidemiologic evidence supported the hypothesis that the vehicle of infection was one lot of summer sausage prepared at and sold from a small combination-locker plant-butcher shop located in Minnesota near the Iowa border.

No Time for Laughing

An eighty-year-old man kept a detailed record of what he had done during each hour of every day and then figured out how he used his time during the entire period of his long life. He spent over twenty-six years in sleep, twenty-one years working, two hundred and twenty-eight days shaving, and one hundred and forty days paying bills. He also spent over twenty-six days scolding his children and two days yelling at his dogs. Only twenty-six hours were spent in laughing.*

The James E. Moore Society

Man's Early Challenge to Neoplasms*

DURING THE PAST SEVERAL decades man has greatly increased his scientific knowledge and understanding of the origins and nature of life and of disease affecting life.

A Neoplasm

The nature and etiology of cancerous processes has defied man to a much greater extent than those of many other illnesses. Cancer is a disease that acts in a very special way: flesh acting insidiously upon itself in a proliferative, uncontrollable and predatory manner. Each lesion is a cancerous process made up of cells derived in most instances from the host organism, which has been so altered that it no longer obeys the laws of a multi-systemed unit where each cell must peacefully co-exist with the other cells. Instead, chaos may occur, with the altered cells so multiplying at the expense of normal cells as to result in the mortality of the host. This process is called neoplastic; the part that is changed by the process is a neoplasm.

Era of Empiricism (to 1761 A.D.)

Early in man's history, mysticism so pervaded all departments of life that many of its ideas still prevail in our medicine and folklore. Considering the length of time that man has dealt with this disease, we must admit that his knowledge of its nature and treatment have not progressed very fast or far. Some of the original descriptions of cancer are still valid even today.

Origin of the Word

The use of the term "carcinoma-cancer" was initiated during Greek times, probably because of the observation that malignant growths had multiple large veins around them. Galen said that these growths were called cancer because: "As a crab is furnished with claws on both sides of the body, so in this disease the veins which extend from the tumor represent with it a figure much like that of a crab;"[22] and in 625 A.D. Paul of Aegina said: "However, some may say that cancer is called such because it adheres with such obstinacy to the part it seizes that like the crab, it cannot be separated without great difficulty."[22]

Occurrence in Ancient Times

Written records of archaeological findings in Egypt and Peru reveal the existence of osteoporosis, osteosarcoma, and osteomalacia. The earliest medical records,[6,7] dating back to about 2500 B.C., were found in China, in India and in the Egyptian papyri. In the Papyrus Ebers (1500 B.C.) a tumor is mentioned, and it is said, that "such a tumor must not be touched," suggesting that the result might be fatal. The only clear description of cancer is that of a lipoma, which was treated "with a knife." In a cuneiform inscription from Nineveh (800 B.C.) cancer of the breast is mentioned. Hebrew writings[5] contain clinical descriptions of symptoms diagnostic of malignant growths.

Early Treatment of Neoplasms

In Greek history Democedes is credited with successfully treating his wife for cancer of the breast. Therapy during that time was based on excision and a variety of escharotics and arsenical ointments. Hippocrates differentiated between scirrhus and carcinoma, the former being a hard and the latter an ulcerating type of cancer. The Hippocratic Canon, the first to employ the terms cancer and carcinoma, contained references to cancer of the breast, stomach, and uterus, and extirpation of a neck cancer by cautery.

Celsus (35-25 B.C.) believed the disease to be generally incurable, but he operated on local ones. He made many diagnoses of cancer by its recurrence after cautery and caused one of his contemporaries to remark: "Cancer is incurable because it cannot be curable; if curable then it is not cancer." Leonides of Alexandria (180 A.D.) was the first to describe retraction of the nipple in breast cancer. He operated on many cases of breast cancer by excision of the breast with a scalpel, making sure in all instances that he was going through sound tissue, and cauterizing the wound to prevent hemorrhage and to destroy the remaining cancer around the incision.

*Presented to the James E. Moore Society on October 8, 1968.

Galen (131-203 A.D.), the great Greek physician during Roman times, described a certain diet to be followed by the cancer patient. Also, by prescribing purgative remedies and bleeding, he sought to influence the course of the tumors.

During the 12th and the 14th centuries, the surgical works of Rolando and of Guy de Chauliac carried on the conservative Galenic attitude toward cancer. Localized and superficial tumors were treated with caustic pastes or excised with the knife and/or cautery. Cancers of any great proportions, however, were left alone. Only one late Renaissance German surgeon, Fabricius Hildanus, carried out comparatively drastic operative resections for cancer, performing in some instances a crude axillary dissection.

Etiology of Cancer

Galen's humoral theory dominated medicine for more than fifteen hundred years. According to this theory, the body was regarded as having four fluids: blood from the heart, phlegm from the head, yellow bile from the liver, and black bile from the spleen. Any abnormal mixture of these resulted in disease. Galen thought that cancer developed from concentration of the black bile, suggesting that the suppression of the menses and the appearance of hemorrhage prevented the discharge of black bile.

Period of Gross Pathology (1761-1838)

Prior to 1761, cancer was often confused with inflammatory processes. During the Renaissance great advances in anatomy and wound surgery were achieved; but pathology did not succeed in escaping from the bounds of the humoral theory. Until the dogma of this theory was discarded and the classification of tumors begun, on the basis of objective findings at autopsy, improvement in diagnosis and treatment was impossible. In the 17th and the 18th centuries new explanations were sought, consistent with newly evolving pathological concepts.

The Nature of Cancer

In 1761, Morgagni,[23] an anatomist, laid the foundations of pathologic anatomy on the organ level, after finding localized cancer in many of his autopsies. He distinguished malignant neoplasms from benign swellings such as aneurysms, strumas, gummas and erosions. A French surgeon, LeDran, at this same time, was the first to totally discard Galen's humoral conception of cancer. He also regarded cancer as a local disease in its early stages and believed it spread systemically via the lymphatics to regional nodes and then into the general circulation. He described fully the path of metastasis to the lung from breast cancer.

Research into the cancer problem was being stimulated by scientific societies. The French Royal Academy of Surgery in 1732 and the Lyon Academy of Science in 1773 offered prizes for original essays on the question: "What is Cancer?" The latter award was won by the surgeon-chemist Bernard Peyrille. He inoculated a dog with fluid from human mammary cancer; but the dog was described as barking so much that Peyrille's housekeeper drowned the animal.

Modern Etiology

In 1775, Percival Potts,[25] studying scrotal cancer in chimney-sweeps, strengthened the concept of chemical and *physical irritants* as aggravants for neoplasma. John Hunter, in his "Lectures on the Principles of Surgery," said: "I would call that cancer which produces the following effects: viz, a circumscribed tumefaction with much hardness and a drawing in of the skin covering it, as if the cellular membrane underneath it was destroyed; then a species of suppuration takes in the center and ulceration of the external surface. . . Cancer is one of the first class of our first division of poisons; viz, that which only produces local effects through it has been supposed to contaminate the constitution, which would be terrible indeed, as we have no specific nor even palliative treatment for it." Upon the cause, he wrote:

> "It has been said that cancers are produced by *ill health* as rheumatisms are; but this arises from the age of cancer being the age of such complaints and being the predisposing cause of both, but not particularly, of the cancerous disposition. The pre-disposing causes are three in number, viz, age, parts involved and *hereditary pre-disposition,* and perhaps *climate* also has a considerable effect though not itself a pre-disposing cause."[9]

He suggested that tumors, although products of lymph secretion, were structurally comparable to normal organs.

The first cooperative group to enter into the study of cancer, following the impetus given by John Hunter, comprised a number of prominent English clinicians who in 1802 organized themselves into "The Society for Investigating the Nature and Cure of Cancer."[1] This society aroused contemporary interest in cancer by sending to medical practitioners a questionnaire which covered many clinical aspects and speculative inquiries designed to obtain a consensus of opinion with regard to heredity, infections, climate, and a host of other factors which might influence the development of cancer. These questions were posed in order to improve clinical observations and diagnostic techniques. A reply to these queries was published by a Dublin surgeon in 1809 who de-emphasized suspected hereditary and infective influences and stressed the constitutional source of cancer as a deficiency of ferrous oxide.

Cellular System

In the French School of Medicine the practice of pathologic anatomy begun by Morgagni was continued by Bichat,[26] who distinguished stroma and parenchyma in rudimentary terms, the former of which he designated a "cellular system" common to all tumors. Laennec[27] implemented these ideas (1812) when he classed cancers among the heterologous, adventitious tissues; tissues which do not have normal organ counterparts but are *de novo* productions of pathologic processes. He attempted to improve the descriptions of neoplasms by observation of microscopically thin sections, but his work in this area was largely disappointing because of limitations in lenses for microscopes. His theories were based on his belief that neoplastic growth was basically a degenerative process. Dupuytren tried to establish the infectiousness of cancer by feeding and inoculating animals with fragments of malignant tissue from humans. Cruveihier believed that the only difference between these forms as described by Laennec stemmed from the relative amounts of "cancer juice" occurring in each. Colloid cancer was distinguished from other types as containing no "cancer juice."

An opposite view was taken by Broussais who felt that neoplasms were manifestations of change in the constitutional "tone" or vigor through alterations in the organism's inherent irritability. He proposed that except for superficially localized instances, cancer, as a generalized consequence of inflammation, was incurable. His research sought its causes in the various pathways of irritation culminating in inflammation. Further modification of this idea was advanced by a colleague (Andral),[3] who defined cancer not as a specific structural lesion but as a product of nutritive alterations and aberrant secretory activities to which inflammation was a contributing cause.

Period of Microscopic Pathology (1839-1900)

Blastema Theory

The application of the achromatic microscope (Müller) to the tumor problem in 1838 constituted one of the major advances in the 19th century to cancer research and diagnosis. Müller noted the predominance of connective tissue in scirrhus, differentiated the stroma of adenoid tumors from their parenchyma and also detected within these cellular groups such things as nuclei, granules, fat bodies, and other inclusions. With this evidence, he tried to correlate clinical symptoms with microscopic appearances. His assumption was that tumors grew from separate germinal elements within the parenchyma. This theory was called the Blastema Theory from which, with modifications, the specific-cell concept evolved.[3] Proponents of this theory suggested the existence of a unique germinal layer, the "cancer blastema," through which all new autonomous growths evolved. Using this principle as the cornerstone of his Cellular Pathology,[30] Virchow considered it possible that cancer originated not from free "blastema" (intercellular plastic lymph), but from the blastema within pre-existing cells. In addition, he assumed that connective tissue played an essential role in the formation of tumors. This theory suggests that the neoplasm begins in the cellular elements of this tissue and then invades the involved tissue.

Epithelial Theory

An early counter-current to Virchow's Connective Tissue Theory was advanced by Carl Thiersch and reinforced by Waldeyer. The former established that epidermal tumors were firmly bound with the connective tissue and that reproduction of the parenchymal element was followed by stromal growth. Thiersch followed these growths in neoplastic alterations with the following conclusions:[3] (a) the stroma, although it sustains epithelial growth in a variety of ways, is not the germinal basis of this growth in health or disease; (b) epithelium possesses its own germinal identity and is the source of distinct formations in health and disease; and (c) it is necessary to alter the thesis that "a tumor is analogous to any other new formation and results from the proliferation of cells of the same general character as the tumor." This is called the Epithelial Theory; it specified that all cancer cells were atypical versions of normal epithelial cells, not of the particular cell, but rather the behavior of the whole group of cells as distinguished by increased mitotic figures, aberrant configurations and other peculiarities of cancer morphology. This theory became the basis of microscopic diagnosis and also directed research into more functional considerations.

Specific Structural Pathology

Between 1820 and 1860, through the efforts of French clinicians, a long established system of clinical diagnoses based upon symptoms yielded to concepts of diseases, each related to localized structural pathology (instead of "inflammation of the chest," they recognized specific entities such as pleurisy, pneumonia, etc.). In cancer, the work of Müller and others between 1850 and 1870 made it possible to differentiate between benign and inflamed lesions and to recognize malignant growths in terms of both symptoms and lesions. It was thus possible to establish a group of clinically identifiable, malignant diseases, and the next step was to find the etiology of this disease called cancer.

Era of Experimental Research (1880 to present)

Predisposition

Virchow in 1858 proposed that the specific cause of cancer was both an irritation and a predisposition of the tissues. Thiersch's theory (1865) of senile disposition or growth-energy-imbalance proposed the idea that diminished stromic resistance occurs, whereby the actively proliferating epithelium is able to establish an advantage over the stroma, thus forming the nucleus of a neoplasm. Neither of these theories was altogether convincing at the time. Cohnheim's "embryonic rest" hypothesis was in reality the successor of earlier ideas of an undifferentiated blastema germinal layer as a source of cancer. He postulated that some defect originating in embryonic life became the focal point of tumor formation, a hypothesis which demands the existence of embryonal inclusions in man. These can be readily found, but there are many more that have not undergone malignant change than that have. For this reason alone, one must disregard this theory; yet a modicum of truth is based on the fact that numerous congenital tumors have been found.

Infectious Etiology

The infectious nature of cancer was first suggested in the 17th century but had to await the rise of bacteriology in the 1870s for the theory to be tested. The existence of a cancer microbe was postulated in 1872 and has been pursued ever since. In 1886, before the New York County Medical Society,[4] McNamara announced that clinical and experimental efforts had so far failed to link a bacterium with the cause of tumors, and tumors have never been successfully inoculated. Concerning the microbic source of carcinoma, he felt that the misplaced epithelial elements could account for all the reactive changes in the cells of the matrix. If a microorganism were to be considered the cause, why should it affect only the epithelial cells? There was no direct evidence at this time that pathogens could produce any more than reactive hyperplasias. The great advantage of proposing an infective origin to malignant processes was that it need not go beyond the organism and its cellular elements to explain the occurrence of malignant growth. In 1887, Scheurlen described a bacillus isolated from human carcinoma. He reported that culture-grown specimens of these organisms when inoculated into dogs produced epitheliomas in which the bacilli could again be isolated; but reappraisal by many other investigators concluded that bacilli were not directly involved in the production of tumors.

Viruses

The infection theory, however, continued to flourish after 1889 through reports of Russell's blastomycete-appearing fuchsin bodies in epitheliomas and Flexner's cellular inclusions in lymphosarcoma, which appeared to be protozoa. By the turn of the century, it was generally agreed by most investigators that cancer could result from an external or internal stimulus, probably a "potent living influence" such as a parasite,[14] and that its discovery would depend upon the adoption of very rigid research techniques. In 1901 Gaylord[15] reported the discovery in human cancer of undifferentiated parasites which, when inoculated into a guinea pig, produced adenocarcinomatous nodules. Preliminary evidence from these studies implicated the reactions of the protozoan inclusions in malignant tissue with those of vaccinia, the virus which by 1900 had been grown upon rabbit cornea. Gaylord's claim of finding the cause of cancer was discredited when attempts to reproduce it in other experimental animals failed. However, with the virus having been hypothesized and with the additional studies of Borrel in 1904 on contagious avian epithelioses, a new phase of the infection hypothesis began. Two Danes, Ellerman and Bang, reported the first tumor virus in 1908.[31,12] They were able to induce six successive passages of it in chickens, producing leukemia in each successive group. Yet this work was not convincing because at this time leukemia was not recognized as a neoplastic disease. In 1910, Peyton Rhous[12] described a malignant chicken sarcoma propagated by transplanting its cells and by their multiplication in the new host. One year later, these cells yielded a causative virus, termed the RSV virus, which has been maintained for more than 55 years in successive transplants.

Transplantation

The concept of cancer as a transmissible disease parallels the early popular beliefs of its contagiousness, found in many past reports of its transfer from one individual to another; the phenomenon of Cancer Houses, the concept of cancer as a plague in ancient days, and instances of its tranfer from patient to physician. Inoculations of human cancer into animals bore significantly on the question of parasite transmission during the 1870-1900 period. Among the efforts were those of two French investigators (Duplay and Cuzinin in 1892[4]) in which fragments of human tumors and those of spontaneous animal tumors were inoculated into a large group of different animals. Duplay and Cuzinin came up with only one positive result in dogs, which led them to question the validity of transplantation studies, especially those from man to animal and those between different animal species.

The priority for the first known successful tumor transplantation is credited to Novinsky who in 1875 succeeded in transplanting a nasal anaplastic tumor through two generations of dogs. In 1889, the first systematic survey of host-tumor relationship was made by Morau[4] who successfully transplanted through seventeen generations of mice a cylinder-cell epithelioma. Five years later he presented the following conclusions: (a) cylindrical epitheliomas of white mice are inoculable only in animals of the same species; (b) heredity plays a considerable role in the development of these neoplasms and prepares the soil for their evolution; (c) the neoplasms become generalized and this process is hastened by trauma; (d) gestation accelerates the evolution of these tumors; (e) neoplasms possess a variable virulence which may eventually lead to the death of the host; (f) neoplasms become progressively less inoculable and virulent in other hosts, provided they are of the same species; and (g) when these neoplasms are not ulcerated, they are devoid of bacteria.

Irritant Etiology

The essentials of the modern cell irritation theory are found in the previously considered views of Virchow and the role of environmental trauma first shown by Potts. The ocurrence of epithelial cancer among workers in the coal tar and paraffin industries was noted in 1875 and discussed from a clinico-theoretical point of view[3,35] with regard to the various carcinogenic effects of tars, roots and tobacco smoke. Among the first to attempt to produce experimental cancer with strictly irritative stimuli was Martin in 1882.[3,36] He administered injections of oil of sweet almonds converted into an irritant with the addition of croton oil, and he found that the animal developed a lung lesion corresponding to an epithelioma. Another investigator in 1889 painted preparations of gas and coal tar upon the skin, vulvae and nipples of dogs for months but managed to produce only local inflammatory changes.

By the turn of the century a number of researchers believed that external stimuli could induce an "anaplastic" process of the cell which involved no change in its position or relationship with neighboring cells. Around 1905, investigators using chemical stimuli showed that certain chemicals caused cellular proliferation but not neoplasms. The first true experimental production of cancer was by Fibiger in 1913 when he was able to feed rats a particular type of cockroach and later, at autopsy, found gastric papillomas and in some cases even carcinoma. In 1916, two Japanese investigators, Yamagiwa and Itchikawa, were able for the first time to initiate the production of a carcinoma with a chemical stimulus. They had applied coal tar two to three times a week to the internal surface of the rabbit's ear (spontaneous tumors had never been previously found there). Two to three months later, warty outgrowths covered with thickened, horny epithelium appeared in the painted area. Later, malignant change set in and infiltration and metastasis became apparent. This was the beginning of what today occupies the talents and time of many researchers working with experimental models, using chemical initiators, and then attempting by other means to reverse the early changes which appear.

Conclusion

Clinical observations, classification and theories of cancer have extended from the dawn of medical history and show that cancer was considered a systemic disease and that only visible cancer was treated. It was not until biological and pathological sciences came into their own in the 18th and 19th centuries that a scientific approach to neoplasms became feasible. Foundations of the present knowledge of oncology rest upon the compound microscope and its use in the study of normal and diseased tissues, facilitated by techniques of tissue preparation and staining. It was then shown that neoplastic diseases are characterized by an abnormal proliferation of cells, which refuse to obey the natural laws of growth. Men like Müller, Hunter, Cohnheim and Virchow were among the investigators of the 19th century whose labors led to the description of tumors, to the differential diagnosis based on biopsy and the course and prognosis of the specific neoplastic processes. So extensive were these studies that few fundamental additions have had to be made to the gross and microscopic studies of morphology.

Now, investigations into the basic cause and reversal of neoplastic mechanisms are our major concern.

On Headaches

Strong and continued headaches with fever, if any of the deadly symptoms be joined to them, are very fatal. But if without such symptoms the pain be prolonged beyond twenty days, a discharge of blood from the nose or some abscess in the inferior parts may be anticipated; but while the pain is recent, we may expect in like manner a discharge of blood from the nose, or a suppuration, especially if the pain be seated above the temples and forehead; but the hemorrhage is rather to be looked for in persons younger than thirty years, and the suppuration in more elderly persons.*

In Memoriam

All that tread the globe are but a handful to the tribes that slumber in its bosom.—Bryant

ALBERT J. EMOND, M.D.

Dr. Albert J. Emond, 67, Farmington physician, died April 10. Born in Minneapolis, Dr. Emond obtained his medical degree at the University of Minnesota. He interned at the Charles T. Miller Hospital in St. Paul and practiced in Hankinson, North Dakota and Minneapolis before going to Farmington.

He was on the visiting staffs of St. Mary's and Fairview Hospitals in Minneapolis and a member of the Hennepin County Medical Society and the American Medical Association. Dr. Emond was an Associate Member of the Minnesota State Medical Association.

He is survived by his wife and son. Dr. Joseph S. Emond of Farmington is his brother.

GEORGE E. HUDSON, M.D.

Dr. George E. Hudson, 75, Minneapolis physician, died April 9. Born in Canada, Dr. Hudson, however, obtained his medical degree at Harvard University Medical School.

He was a member of the Hennepin County Medical Society and the American Medical Association and an Associate Member of the Minnesota State Medical Association.

He is survived by his son and two daughters.

ARTHUR I. ARNESON, M.D.

Dr. Arthur I. Arneson, 77, Morris surgeon, died April 10. Born in Emmons, he received his medical education at the University of Iowa, later moving to Austin where he practiced medicine there and in Starbuck.

Dr. Arneson was an enthusiastic fisherman, big game hunter and outdoors photographer. He was well-known for his interest and leadership in conservation activities, and his outdoor films were of such professional quality that he was called upon to show them before many sportsmen's groups.

He was a member of the Board of Directors of the Lakeland Mental Health Center, Fergus Falls, a member of the American Association of General Practitioners, the West Central Minnesota Medical Society, the American Medical Association and a 50 Club Member of the Minnesota State Medical Association. In 1965 Dr. Arneson was named recipient of the WCCO Radio "Good Neighbor Award," an honor bestowed upon persons who had contributed to an unusual degree to the betterment of their communities and the state.

Dr. Arneson is survived by his wife and two daughters.

HERBERT Z. GIFFIN, M.D.

Dr. Herbert Z. Giffin, 90, last survivor among a half-dozen doctors practicing with Doctors Will and Charles Mayo when they formed the Mayo Clinic, died April 25.

A native of Kirkwood, N. J., and a graduate of Johns Hopkins University, Dr. Giffin joined the Mayo group in 1906, serving as a specialist in diseases of the blood.

He was a member of the Zumbro Valley Medical Society, Southern Minnesota Medical Association, Minnesota Society of Internal Medicine, Minnesota Academy of Medicine, Central Interurban Clinical Club, Central Society for Clinical Research, American Medical Association, American Association for Advancement of Science, Association of American Physicians, American Society for Clinical Investment and a 50 Club and Life Member of the Minnesota State Medical Association. Dr. Griffin was a former president of the Minnesota State Medical Association and the winner of its distinguished service medal.

He is survived by his wife, two sons, and a daughter, Dr. Mary E. Griffin, of Winnetka, Illinois.

EARL ARTHUR SCHULTZ, M.D.

Dr. Earl A. Schultz, 45, died in Mt. Sinai Medical Center in Los Angeles, California, April 26. Born in Winnipeg, Canada, Dr. Schultz was a graduate of the Faculty of Medicine, University of Manitoba, Winnipeg. His post-graduate work in anesthesiology was done at the University of Minnesota Hospitals.

He was a member of the Hennepin County Medical Society, certified by the American Board of Anesthesiology, a member of the University of Minnesota faculty, member of the American Medical Association and the Minnesota State Medical Association.

He is survived by his sister.

WILLIAM F. MC MANUS, M.D.

Dr. William McManus, 55, practicing physician in Princeton since 1946, died February 23, in Albuquerque, New Mexico. The family had moved to New Mexico last October.

A graduate of Loyola University in Chicago, he received the Blue Key Honor and a teaching fellowship, upon completion of his post-graduate work. He was a member of the American Medical Association, West Central Minnesota Medical Society and the Minnesota State Medical Association. Dr. McManus founded the McManus Clinic in Princeton.

He is survived by his wife and children.

The Fortunate One.

Her urinary tract infection reveals itself through pain and discomfort.

While the pain and discomfort of a G.U. infection are anything but pleasant, the patient may be luckier than she realizes. That burning sensation (and/or frequency, urgency, dysuria) is a usually reliable sign of a urinary tract infection. And it's her good fortune that her infection won't go undetected...or untreated.

Azo Gantanol® therapy usually provides analgesic action within one-half hour, while control of the infection begins within two hours. Azo, a specific urinary analgesic, soothes inflamed mucosa to give symptomatic relief. At the same time, the antibacterial component, Gantanol (sulfamethoxazole), achieves therapeutic levels in the blood and urine, with diffusion into interstitial fluids. Azo Gantanol—a good choice when urinary tract infection reveals itself through symptomatic distress.

Before prescribing, please consult complete product information, a summary of which appears on opposite page.

Azo Gantanol®

(Each tablet contains 0.5 Gm sulfamethoxazole and 100 mg phenazopyridine HCl.)

Azo for the pain
Gantanol®
(sulfamethoxazole)
for the pathogens

Before prescribing, please consult complete product information, a summary of which follows:

Indications: Urinary tract infections with associated pain or discomfort when due to susceptible organisms; prophylactically in urologic surgery, catheterization and instrumentation.

Contraindicated in sulfonamide-sensitive patients, pregnant females at term, premature infants, newborn infants during the first three months of life, glomerular nephritis, severe hepatitis, uremia and pyelonephritis of pregnancy with gastrointestinal disturbances.

Warnings: Use only after critical appraisal in patients with liver damage, renal damage, urinary obstruction or blood dyscrasias. If toxic or hypersensitivity reactions or blood dyscrasias occur, discontinue therapy. In closely intermittent or prolonged therapy, blood counts and liver and kidney function tests should be performed.

Precautions: Observe usual sulfonamide therapy precautions including maintenance of an adequate fluid intake. Use with caution in patients with histories of allergies and/or asthma. Patients with impaired renal function should be followed closely since renal impairment may cause excessive drug accumulation. Occasional failures may occur due to resistant microorganisms. Not effective in virus and rickettsial infections.

Adverse Reactions: Headache, nausea, vomiting, urticaria, diarrhea, hepatitis, pancreatitis, blood dyscrasias, neuropathy, drug fever, skin rash, Stevens-Johnson syndrome, injection of the conjunctiva and sclera, petechiae, purpura, hematuria or crystalluria may occur, in which case the dosage should be decreased or the drug withdrawn.

Dosage: Adults—4 tablets initially, then 2 tablets morning and evening.

How Supplied: Tablets, bottles of 50.

What's New?

Mead Johnson Laboratories

U. S. Department of Agriculture studies indicate that calcium with its high daily requirement is one of the nutrients most often deficient in American diets.

Mead Johnson Laboratories has announced a new product, SPAR-CAL, which makes calcium—and the vitamin D necessary for its absorption and utilization—available in a pleasant-tasting form.

The orange-flavored, effervescent tablet dissolves quickly in six ounces of water and provides 500 mg. of elemental calcium (66% of MDR) and 200 USP units of vitamin D.

SPAR-CAL is indicated in calcium deficient diets, in pregnancy, during periods of rapid growth and in allergy or dislike of milk.

Individually-wrapped tablets come in packages of 30.

Eli Lilly and Company

Eli Lilly and Company announced a change in the dosage form of Ilosone Liquid (erythromycin estolate). This new preparation provides 250 milligrams per 5 cc teaspoonful, twice the dosage strength of the preparation which was first offered in 1967.

Kibitzers

One thing about a house-call's this:
There's always someone, man or miss,
An uncle, sister, father, brother,
A cleaning woman, or some other,
Who hovers close with piercing questions
And admonitions and suggestions.

Sometimes a neighbor happens by
To lend a hand (and tongue and eye)
And tell, although she isn't bid,
The wondrous things her doctor did
And make you feel an awful fool
With need of going back to school.

A doctor merits extra salary
For working when he has a gallery.*

Toxicity in Cancer Chemotherapy

(For Answers Dial for Tape #16)

1. What are the 4 steps in combatting the nausea, vomiting and diarrhea which are side effects of many drugs used in cancer chemotherapy?
2. Two simple remedies may help in the management of stomatitis. They are:
   a) avoidance of................
   b) administration of............
3. When handling a patient who is receiving chemotherapy the W.B.C. should be performed at regular intervals. What should be done if the count:
   a) drops below 3,000/mm^3 ?
   b) drops below 2,000/mm^3 ?
4. What is the management of post-chemotherapeutic thrombocytopenia with ecchymoses?
5. What is the prognosis of alopecia following cancer chemotherapy?

Tetanus Prophylaxis

(For Answers Dial for Tape #21)

1. Burns are an indication for tetanus antiserum. True or False?
2. Under what circumstances is the administration of 0.5 ml tetanus toxoid *adequate* prophylaxis following a severe injury in a street accident?
3. What antibiotics are effective in the prevention of tetanus?
4. What is the only remaining indication for equine tetanus antitoxin?

Congestive Heart Failure in Infants

(For Answers Dial for Tape #43)

1. The incidence of congenital abnormality of the heart in the newborn is: a) 0.006% b) 0.06% c) 0.6%
2. The mortality in infants with congenital heart disease developing congestive failure under one month of age is: a) 20% b) 40% c) 60% d) 80%
3. There are 4 cardinal symptoms of congestive heart failure in infancy. Which of these is related to pulmonary venous pressure?
4. The digitalizing dose of Digoxin is calculated on the basis of weight. The usual dose in mgms/Kg body weight is: a) 0.008 mgms b) 0.08 mgms c) 0.8 mgms

Minnesota Medicine at a Glance

Anuria Secondary to Ethylene Glycol Intoxication—*Smith et al.* Page 1049

Ethylene glycol intoxication usually causes death by kidney damage which is reversible. An alcoholic male entered the hospital after four days of anuria; ethylene glycol intoxication was diagnosed by a finding of calcium oxalate crystals in renal biopsy. He survived after treatment with peritoneal dialysis and hemodialysis.

Vascular Compression of the Distal Duodenum—*Imes* Page 1055

The symptomatic compression of the third portion of the duodenum by the root of the mesentery may occur more frequently than is now commonly diagnosed. The author reports 11 cases discovered while doing 1643 upper gastrointestinal x-ray examinations over a 14-month period. The anatomic basis, the symptoms, the diagnostic x-ray findings, and the treatment are discussed.

Congenital Pseudarthrosis of the Ulna—*Shertzer et al.* Page 1061

Two cases of an interesting orthopedic anomaly are discussed, illustrating the progressiveness of the condition if left untreated and the difficulties in its correction.

Hospital-Acquired Infections—*Oh et al.* Page 1067

Hospital-acquired infections during a six-month period, January through June 1967, on six surgical stations were analyzed. The overall infection rate was 5.2%. *Staphylococcus aureus* accounted for more infections than any other single bacterial species. However, enteric gram-negative bacteria accounted for more than one third of the hospital-acquired infections.

The antibiotic therapy prior to documentation of hospital-acquired infection was reviewed. Infection with gram-negative bacteria occurred with nearly equal frequency in patients being treated with antibiotics as in those not receiving antibiotics. Hospital-acquired infections with gram-negative enteric bacteria were most frequently found in patients receiving broad spectrum antibiotics.

Giardia lamblia as Parasite in Humans—*Mears and Zinneman* Page 1107

Giardia lamblia is found in human stool all over the world, even in the United States. Three cases from the Minneapolis Veterans Hospital are reported. It is associated with diarrhea, other gastrointestinal symptoms, nervousness and anemia but there is a question of pathogenicity. The history of the discovery and the life cycle of the parasite is discussed.

Cholecystocolonic Fistula—*Snider and Judd* Page 1141

A 20-year review of cholecystocolonic fiistulas seen at the Mayo Clinic is presented along with a detailed case report.

Special Issue
Cardiology Prevention

Dear Doctor,
You made me
what I am today–
a whole lot
slimmer!

TEPANIL—the right start in support of the weight-control program *you* recommend. It reduces the appetite. Doesn't kill it. Weight loss is significant—gradual—yet there is a relatively low incidence of CNS stimulation. Because TEPANIL works on the appetite, not on the "nerves."

Contraindications: Concurrently with MAO inhibitors, in patients hypersensitive to this drug; in emotionally unstable patients susceptible to drug abuse.

Warning: Although generally safer than the amphetamines, use with great caution in patients with severe hypertension or severe cardiovascular disease. Do not use during first trimester of pregnancy unless potential benefits outweigh potential risks.

Adverse Reactions: Rarely severe enough to require discontinuation of therapy, unpleasant symptoms with diethylpropion hydrochloride have been reported to occur in relatively low incidence.

As is characteristic of sympathomimetic agents, it may occasionally cause *CNS effects* such as insomnia, nervousness, dizziness, anxiety, and jitteriness. In contrast, CNS depression has been reported. In a few epileptics an increase in convulsive episodes has been reported.

Sympathomimetic *cardiovascular effects* reported include ones such as tachycardia, precordial pain, arrhythmia, palpitation, and increased blood pressure. One published report described T-wave changes in the ECG of a healthy young male after ingestion of diethylpropion hydrochloride; this was an isolated experience, which has not been reported by others.

Allergic phenomena reported include such conditions as rash, urticaria, ecchymosis, and erythema.

Gastrointestinal effects such as diarrhea, constipation, nausea, vomiting, and abdominal discomfort have been reported.

Specific reports on the hematopoietic system include two each of bone marrow depression, agranulocytosis, and leukopenia.

A variety of miscellaneous adverse reactions have been reported by physicians. These include complaints such as dry mouth, headache, dyspnea, menstrual upset, hair loss, muscle pain, decreased libido, dysuria, and polyuria.

Convenience of two dosage forms: TEPANIL Ten-tab tablets: One 75 mg. tablet daily, swallowed whole, in midmorning (10 a.m.); TEPANIL: One 25 mg. tablet three times daily, one hour before meals. If desired, an additional tablet may be given in midevening to overcome night hunger. Use in children under 12 years of age is not recommended.

Tepanil® Ten-tab®

(continuous release form)

(diethylpropion hydrochloride)

DECLOSTATIN® 300

Demethylchlortetracycline HCl 300 mg
and Nystatin 500,000 units
CAPSULE-SHAPED TABLETS Lederle

b.i.d.

To guard susceptible patients against intestinal monilial overgrowth during broad-spectrum therapy—the protection of nystatin is combined with demethylchlortetracycline in DECLOSTATIN.

For your susceptible candidates, prescribe DECLOSTATIN—the broad-spectrum therapy that prevents monilial overgrowth.

Effectiveness: Because its antibacterial component is DECLOMYCIN Demethylchlortetracycline, DECLOSTATIN should be equally or more effective therapeutically than other tetracyclines in infections caused by tetracycline-sensitive organisms. The antifungal component, Nystatin, protects against superinfection by antibiotic-resistant fungal overgrowth (particularly monilia) in the intestinal tract.

Contraindication: History of hypersensitivity to demethylchlortetracycline or nystatin.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Con
stant observation is essential. If new infections appear, appropriat
measures should be taken. In infants, increased intracranial pressur
with bulging fontanels has been observed. All signs and symptoms hav
disappeared rapidly upon cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, dia
rhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculopa
ular and erythematous rashes; a rare case of exfoliative dermatitis ha
been reported. Photosensitivity; onycholysis and discoloration of th
nails (rare). Kidney—rise in BUN, apparently dose related. Transien
increase in urinary output, sometimes accompanied by thirst (rare
Hypersensitivity reactions—urticaria, angioneurotic edema, anaphylaxi
Teeth—dental staining (yellow-brown) in children of mothers given thi
drug during the latter half of pregnancy, and in children given the dru
during the neonatal period, infancy and early childhood. Enamel hyp
plasia has been seen in a few children. If adverse reaction or idiosy
crasy occurs, discontinue medication and institute appropriate thera
Demethylchlortetracycline may form a stable calcium complex in an
bone-forming tissue with no serious harmful effects reported thus fa
in humans.

Average Adult Daily Dosage: 150 mg q.i.d. or 300 mg b.i.d. Should b
given 1 hour before or 2 hours after meals, since absorption is impaire
by the concomitant administration of high calcium content drugs, food
and some dairy products. Treatment of streptococcal infections shoul
continue for 10 days, even though symptoms have subsided.

President's Letter

THROUGHOUT MOST of recorded history, man has extolled the heart as the seat of the mind and the soul both in music and verse. The "heart" over the centuries has played an important part in our daily lives, as witness the numerous familiar expressions which have accumulated over the ages. No less a scholar than Aristotle proclaimed the heart as the seat of intelligence. In this issue of MINNESOTA MEDICINE, we are proud to give you a more scientific slant on the heart as it really is.

The Minnesota Symposium on Prevention in Cardiology contained in this special issue of MINNESOTA MEDICINE is *must* reading for all physicians regardless of specialty training or interests. Most doctors have a deep interest in cardiovascular disease and especially coronary thrombosis because of its high incidence in physicians. We doctors have a self-interest in the causes of heart disease; likewise we are constantly seeking to learn more of the methods to prevent heart attacks. This special issue therefore is an excellent review for all of us as well as a means of updating our knowledge in this field. The authors and contributors are to be highly complimented for this excellent and rewarding symposium.

For more than a decade and a half, cholesterol has been incriminated in the minds of many researchers as the principle cause of coronary thrombosis as against heredity, obesity, stress, to mention only a few of the many possible contributors to coronary heart disease. This symposium puts cholesterol in better perspective in relationship to coronary thrombosis. Serum lipid fractions, saturated and unsaturated fats, diets, hyperlipidemia, obesity, elevated blood sugar, hypertension, cigarette smoking, physical inactivity and exercise are all covered in depth in this series and make most interesting reading.

To become a quasi-authority on the prevention of cardiac disease don't miss studying this issue of MINNESOTA MEDICINE. If you want to learn how to improve and protect your own heart and blood vessels, do likewise.

We are constantly bombarded by almost every one about the need for more physicians, expanding medical school admissions and building more medical schools. It may be that *Prevention of Coronary Thrombosis in Physicians* would help the doctor shortage a mite.

I would also like to take this opportunity to call to your attention the September issue of MINNESOTA MEDICINE as additional *must* reading. This special issue will contain papers on Chronic Respiratory Disease in Children and Adolescents. These papers are taken from a Continuation Course on Chronic Respiratory Disease held at the University of Minnesota in September of 1968. Those selected are most interesting and informative as well as most practical, providing right up-to-date knowledge on Respiratory Disease. The authors are to be congratulated on these excellent papers.

So let's get educated on heart attacks and lung disease.

Equipment and supplies for the medical profession since 1919

Welcome

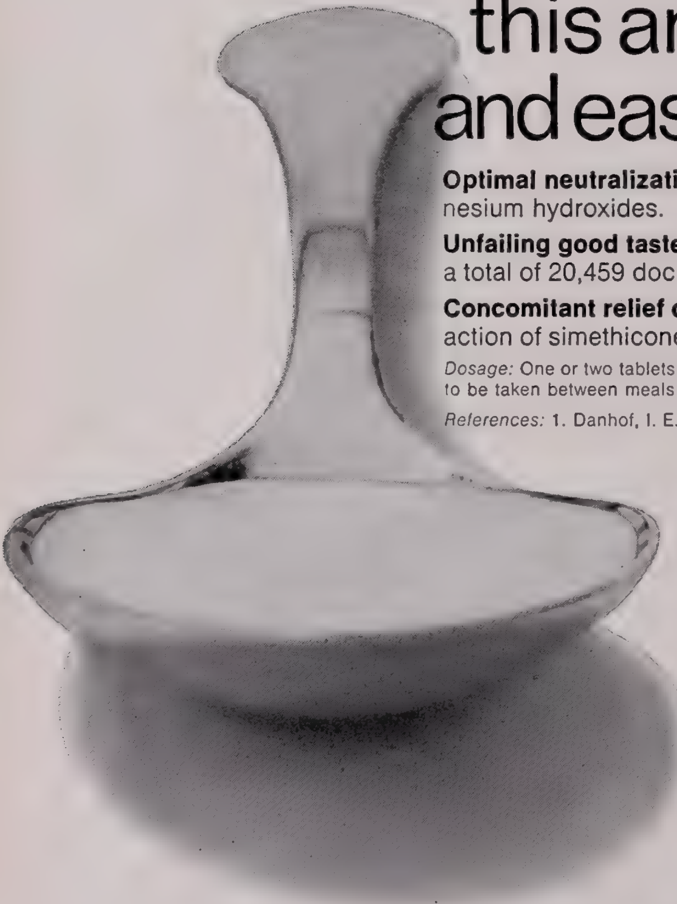
Ladies and gentlemen, good morning. It is my very pleasant responsibility to welcome you to Minnesota, to Rochester, and to the Mayo institutions. At a time when coronary heart disease has reached epidemic proportions in the western world, it is particularly appropriate to spread the gospel of preventive medicine and to disseminate all available information about reducing the risks of atherosclerosis. We are beyond the stage when this type of information can be regarded as of interest only to the epidemiologist or the clinical investigator. It must be made available to, and used by, the medical practitioner who now spends his time almost exclusively with diagnosis and treatment rather than prevention. And that is what this symposium is all about.

The Minnesota Heart Association is proud to be a cosponsor of this symposium on prevention in cardiology. Dr. Henry Blackburn, chairman of our association's Professional Education Committee, deserves great credit for organizing the program and assembling the distinguished participants from this country and abroad. Others who have worked on the local arrangements are Drs. Kenneth G. Berge, Stewart L. Nunn, and John A. Spittell, Jr. With a "Thank you" to these gentlemen, I once more bid you "Welcome" and turn the podium over to Dr. Henry Blackburn.

John L. Juergens, M.D.*
Rochester, Minnesota

---

*Former President, Minnesota Heart Association. Associate Professor of Medicine, Mayo Graduate School of Medicine (University of Minnesota), and Consultant, Section of Medicine, Mayo Clinic, Rochester.



the thousandth teaspoonful

Peptic ulcer patients find the thousandth dose of this antacid as effective and easy-to-take as the first!

Optimal neutralization—provided by the combination of aluminum and magnesium hydroxides.

Unfailing good taste—confirmed by 87.5% of 104 patients in one study, after a total of 20,459 documented days on Mylanta Liquid or tablets.[1]

Concomitant relief of G. I. gas distress—provided by the proven antiflatulent action of simethicone.[2]

Dosage: One or two tablets (well chewed or allowed to dissolve in the mouth); one or two teaspoonfuls to be taken between meals and at bedtime, or as directed by physician.

Introduction*

THE ANALOGY is far from perfect, but I like to think of the development of the epidemiological study of cardiovascular diseases as occurring in Classical, Romantic and Modern periods, like those of serious music. The Classical Period provided an important base, with classic epidemiological compilation and study of International Vital Statistics on Causes of Death. The apparent national differences found in cardiovascular mortality gave an initial impetus to, and clues for, further study. The Romantic Period was one in which a few distinguished physicians and scientists, led by Paul Dudley White and Ancel Keys, made their peripatetic rounds in many varied and exotic places. They obtained important clinical impressions of cultural differences in the frequency of cardiovascular diseases and focused world-wide attention on the great implications of such differences. The Modern Period is characterized by systematic and long-term studies of cardiovascular manifestations in natural populations, measurement of personal characteristics, and active experimental intervention on factors of risk.

Follow-up study of apparently healthy persons has led to estimates of future risk of coronary attack, based on measurement of predisease attributes. The relative importance of these factors and their interaction are now being elucidated. Here, today, the means and the effects of modifying factors of risk will engage us.

The time is appropriate for a call to greater investigation into the possibilities of prevention of cardiovascular diseases and the wider application of current knowledge in attempts to reduce their toll. It is appropriate to sound this call in Minnesota, where so many have been concerned with preventive cardiology, and in Rochester, where the Mayo Clinic holds the respect of all for its practice of diagnostic and therapeutic medicine.

We are most grateful for the pleasant host arrangements in this quiet, single-minded medical community. We owe these arrangements, and the gracious hospitality of the Clinic, to Kenneth Berge and John Spittell, Stewart Nunn and John Juergens, as well as to Helen Bies of the Minnesota Heart Association. The Mayo Clinic and Foundation, and the staff of the Minnesota Heart Association, are available to assist you.

We are pleased now to introduce a distinguished faculty, one which has the richest experience available in the evaluation and attempted reduction of the risk of coronary and hypertensive disease.

Paul Dudley White of Boston, and of the World at Large, once stood alone with a depth of clinical knowledge and a remarkable breadth of understanding of heart diseases. Because he stood strong and with curiosity, vision, and diplomacy, he no longer stands alone but is rather conjoined in a large and important medical enterprise, Preventive Cardiology. Each of us here owes him a professional debt for our own emerging understanding of the distribution, causes, and control of heart diseases. Many more people will come to owe their well-being to Paul White. This is because he so effectively raised the professional challenge of prevention in cardiology and because he provides such a personal challenge to all for living more balanced lives.

The Challenge of Prevention

PAUL DUDLEY WHITE, M.D.
Boston, Massachusetts

IT IS MY FUNCTION to set the stage for this symposium historically, and perhaps romantically, and to outline some of the major problems of the challenge.

We have doubtless always had cardiovascular diseases and much the same kinds or etiologic types that we have today, but also in all probability in different total prevalence and relative incidence. We can do little but guess how common heart disease was in toto or in each separate kind before the days of autopsies. However, in the Bible and especially in the writings of Pliny the Elder sudden deaths were recorded which were instantaneous enough to have been due to coronary insufficiency and ventricular fibrillation. At other times there were recorded more slowly evolving deaths due quite likely to myocardial infarction.

With the descriptions of post-mortem examinations in the sixteenth and seventeenth centuries we find other cardiovascular diseases identified, especially infected and deformed heart valves, enlarged atria and ventricles, aortic aneurysm, and pericarditis. In the eighteenth century congenital lesions and coronary disease were described, as well as the symptom of angina pectoris and the signs and symptoms of heart failure. Another century went by, however, before hypertensive heart disease came into its own as an important and quite common type.

Heart Disease in the Twenties

When I was a very young doctor we were still in the dark ages; then in the 1920s we began to move ahead trying to learn the overall prevalence of cardiovascular disease and the incidence of the various types.

Infectious Heart Involvement

Rheumatic heart involvement, both acute and chronic, made up about half of all our cases. Syphilis and aortic aneurysms were still common, and hypertension ranked second as an etiological type. Diphtheria was still a potent threat to the myocardium.

---

*Presented at the Minnesota Symposium on Prevention in Cardiology, May 2-3, 1968 in Rochester, Minnesota.

The Electrocardiogram

Clinically significant atherosclerosis of the coronary arteries was low on the list, although we had become acquainted with its diagnosis both symptomatically and objectively, especially with the help of the electrocardiogram. Relatively rare in our figures were congenital heart patients who infrequently sought help because none was available. A statistical study by Duckett Jones and myself in the 1920s noted the incidence of congenital cardiovascular defects as 1.5 per cent, while 25 years later in a similar study we found it responsible for 7.9 per cent of 3,000 so-called cardiacs. There were also 3.0 per cent thyrocardiacs, now rarely seen.

Heart Disease in the Sixties

We have made considerable strides, sometimes fortuitously, in the reduction of the prevalence, incidence, and mortality from the infectious types of heart disease, especially the rheumatic, which has dropped far down the scale, though it still exists, especially in parts of the world where preventive measures are few or nil, as in some parts of Central Africa where one sometimes sees tight mitral stenosis in children.

Other infectious types have also been controlled in large part: diphtheria, syphilis, and subacute bacterial endocarditis. Hypertension of certain recognized etiologies and even "essential" hypertension have declined a good deal in the mortality column, under medical treatment.

This leaves two major causes of cardiovascular disease almost untouched, at least so far as their prevention is concerned: congenital heart disease and coronary heart disease. In this program we are concerned with coronary heart disease, but I hope that when we know more about genetics and pay more attention to the health of the human fetus, and even before we have reduced in major degree both the prevalence and the mortality of coronary heart disease, especially in young and middle aged males, we may begin to plan more of an attack on congenital defects. These may eventually constitute our major cardiovascular challenge.

We must now concentrate on atherosclerotic and thrombotic disease, not only of the coronaries but also of the aorta, the cerebral and renal arteries, and those to the legs, for it is the same process which affects them all: both sclerotic and thrombotic.

Coronary Heart Disease

Why is there a greater challenge now than when I was a young cardiologist nearly 50 years ago? Let me list five of the various reasons for our concern:

Prevalence of the Disease

There has been an increasing prevalence of coronary disease as well as an increased incidence. Austin Flint in 1866 and Osler in 1892 called angina pectoris rare, and they knew the symptom well. I am quite sure that I was as able to determine by careful history in the 1920s as I am in the 1960s the presence of symptoms and signs of the disease, including the diagnosis of angina pectoris, and to recognize the electrocardiographic abnormalities and the collateral signs of acute myocardial infarction long before coronary angiography. I was specializing in the whole field of cardiology as I am now and seeing the same number of, or somewhat more, cardiacs, both new and old. In 1924 it took me two years to see 100 new patients with coronary heart disease in contrast to one year in 1965.

A careful scrutiny of my own ward patients in 1912 and 1913, before we had an electrocardiograph, has revealed very few cases of angina pectoris, and only one case of myocardial infarction found at autopsy. I have also looked over electrocardiographic glass plates of the first hundred of our patients in 1914 and found only one case with typical acute myocardial infarction and one with complete heart block. Another clue to the relative infrequency of coronary heart disease as a clinical problem compared to other subjects like rheumatic heart disease was that in the first 100 of my published papers only two concerned coronary heart disease, whereas from 1946 to 1957 inclusive there were 21 such papers out of 99 publications.

The Age of the Coronary Patient

We all have had the experience that of late we have been seeing younger and younger males with coronary heart disease. This was strongly supported by a report by Samuel Levine, who analyzed in 40 families the age of onset of angina pectoris in father and son. He found that the sons began having angina 13 years younger than had their fathers and that their deaths also occurred at a younger age. This fits in with my own experience. I have compared the ages of 100 new patients seen between 1924 to 1926 with those of 100 similar cases seen between 1964 to 1965. There were 5 per cent in the 1960s under the age of 40 compared to 1 per cent in the 1920s, and 21 cases under 50 in the later group compared to seven in the earlier. It was Sam Levine's belief, as it is mine, that something has happened in the last generation which may explain these differences.

Sex

One hundred years ago the wife in the U.S.A. outlived her husband by about one and a half years, but now this advantage has changed to an average of six years. It is clear that atherosclerosis and thrombosis of the coronary cerebral arteries and aorta are responsible, in the main, for this difference. The longevity of the husband must be increased to match, so far as possible, that of his wife. It may be that a shorter male life is a law of nature, but some improvement at least should be possible. In the series of 100 new cases of coronary heart disease of my own there were 72 men and 28 women; of the 21 patients under 50 years of age, 19 were men and only two were women; of the five cases under 40, all were male. In two separate series of 100 cases under the age of 40 years, studied years ago by Sam Levine and myself, 193 were men and only seven were women.

Heredity

How much of the responsibility is to be credited to the genes and how much to the environment is not known. It is possible that the relative responsibility of these factors may vary from family to family and from person to person. Studies of a few thousand coronary-ridden families might determine what changes in their environment would improve their longevity and health.

Occupation

Years ago when I was a young doctor we had a good many real laborers in this country. Most of their hearts were sound, unless they had had rheumatic fever or syphilis, but I recall that their radial arteries were beaded. It was the affluent white collar executive and capitalist who occasionally had coronary heart disease then. Now the situation seems to be reversed. The 'laborer' no longer labors but owns an automobile and gets the richest cuts of beef and puts on pounds of weight; in middle age his coronary arteries become beaded and occluded while his radial arteries remain smooth.

Meanwhile the executive has become wiser and, with the help of his wiser doctor, tries to keep physically fit and is beginning to benefit. Incidentally, I have been trying to persuade groups of young people in this country and overseas to rebel not against their parents but against their parents' bad habits. Sometimes I am viewed with concern as a Don Quixote sparring with windmills; but my experience over a long life in seeing and following up a great many patients makes me believe that the next generation may benefit from our efforts, though it may be difficult to rehabilitate the fathers, even with transplants.

Smoking

A custom loathsome to the eye, harmful to the brain, dangerous to the lungs, and in the black stinking fume thereof, nearest resembling the horrible Stygian smoke of the pit that is bottomless.—James I of England

---

Our models are lenses, coloring the world with as many different hues.—Emerson

The Wages of Excess

"Surely, kings must think that their stomachs are not made like other men's."

These were the rueful words of Luis de Quijada, Chamberlain to Holy Roman Emperor Charles V—commenting on his master's gluttony.

Disabling, agonizing gout attended the monarch's excessive gourmandizing—whether retributive in nature or merely correlative, who can say categorically! His biographer mentions "the highly-spiced dishes, the disgusting sausages, the forbidden fish, the early morning draughts of ale which had been placed outside the window for the frosty night to cool," and gives the following staggering catalogue of Charles' consumption for one day.

"The five o'clock beer was followed by a bowl of chicken broth, improved by milk, sugar and spices. At midday he ate a heavy dinner—roast mutton, for instance, succeeding large slices of beef, followed in turn by braised hare, and that by chicken—all being bolted, for he could not chew. After Vespers he would take a hasty snack, while midnight closed upon a substantial supper. When an Italian doctor warned him that he must give up beer, he flatly answered that he would not."*

No less than eleven periodic attacks of gout—the fifth one of quadruple dimensions—punctuated the Emperor's strenuous reign (1519-1556), descending suddenly to incapacitate their victim at critical junctures: a diplomatic confrontation, an Imperial Diet, a Papal conference, a Cortes session, a military enterprise. For in his vainglorious but doomed dream of unifying a fragmenting Empire, Charles was always on the move, traveling hither and yon throughout his vast dominions in response to political, religious, and military challenges.

With each attack of gout he had to either postpone or abandon his immediate objective and become virtually immobilized until he improved sufficiently to continue his royal expedition. Sometimes, in his later years, he had to be carried on a litter, which he insisted be an open one so that people could see that he was alive. During each attack he curbed his appetite—either by necessity or as a gesture of compliance toward his doctors. But after he recovered he flouted their orders and resumed his gargantuan consumption of food and drink.

While gout constituted Charles' major nemesis there were also numerous other chronic maladies of long standing: erysipelas, trauma from a fall off a horse, asthma, insomnia, general exhaustion.

Eventually he was obliged to capitulate to shattered health when he was stricken at Brussels by something he himself designated as "not gout" and his biographer fails to identify—except that it involved "fever." So, having failed to achieve his magnificent obsession of political consolidation and religious union for his Empire, Charles abdicated—to live another two years in retirement—without, however, renouncing his ravenous appetite.

Editor's Note: How does the student of human nature account for such paradoxicality as Charles' life illustrates? Why did his prodigious determination, herculean endurance, and invincible spirit in pursuing an ever-fading dream not deter him from the grossest self-indulgence? Perhaps psychologists can provide a glib answer. But answers come too easy! For who can really probe the deep dark intricacies of another man's soul!

---

The Essentiality of Prevention

ANCEL KEYS, Ph.D.†
Minneapolis, Minnesota

FOR SEVERAL DECADES we and the general public have been congratulating ourselves on "the spectacular advances of medical science" and "the miracles of modern medicine." There is much, indeed, to rejoice about in all fields of medicine, including cardiology.

For the rheumatic heart patient there are antibiotics against infection, drugs to suppress progressive damage, and finally surgical repair. For the congenital heart patient there is vastly improved diagnosis and the surgeon's new ability to patch up the mistakes of development. The hypertensive heart patient has drugs to lower his blood pressure; the cor pulmonale patient can at least be made less miserable for a while. For the coronary patient there are anticoagulants and intensive care units. For all cardiacs there are defibrillators and cardiac pacers and drugs to combat arrhythmias and failure. Finally, when all else fails, we look at Dr. Blaiberg walking around with his new heart and we read a forecast that before long a thousand teams of surgeons may be busy installing nuclear-powered contraptions to replace hearts diseased beyond redemption.

Prevention

In spite of all advances in diagnosis and treatment, prevention is essential for any real control over most of the heart disease problem.

No Miracles

Not only is prevention always better than cure, but for most of the victims of heart disease there can be good, sometimes remarkable success: management but no cure. Some congenital and rheumatic-fever heart patients

---

Data cited here were obtained with help grants in aid from the U.S. Public Health Service (HE 04697, HE 04997, HE 04754, HE 04774), from the American Heart Association, New York, from the California State Olive Advisory Board, and many other sources to be acknowledged in later fuller publication.

†Professor and Director, Laboratory of Physiological Hygiene, University of Minnesota.

can be actually "cured" by surgery; some hypertensive hearts may be made nearly normal by treatment of the basic high blood pressure; but even if all such congenital, rheumatic fever and hypertensive patients had the most successful treatment, most of the heart disease problem would remain. Coronary heart disease makes up the bulk of this great remaining burden.

Prevention Is Possible

There is no dissent from the proposition that prevention is desirable, but it is instructive to consider some data on life expectation that indicate the poor net outcome of therapeutic advances. The most spectacular improvements in diagnosis and treatment have come since World War II. Table 1 shows the life expectation of white persons in the United States. At the end of the 1940s, 40-year-old men had an average life expectation of 31.2 years; 15 years later the figure was 31.7 years. Women aged 40 did better: at the end of the 1940s their expectation was 4.4 years longer than that of men, and 15 years later their advantage had advanced to 5.8 years. The net improvement in life expectation after age 40 from all medical advances has been appreciable for women, negligible for men.

TABLE 1

Life Expectation of White Persons Aged 40 in the United States

	Years Remaining	
Period	Men	Women
1949-51	31.2	35.6
1959-61	31.7	37.1
1965	31.7	37.5
Gain, 1950 to 1965	0.5	1.9

Incidence of Death

Consideration of the causes of death (Table 2) explains much. For white men aged 40 to 59 the death rate from all causes fell by only 7 per cent over these years; for women of the same age the improvement was 16 per cent, so that now their total death rate is less than half that of men. For the men the death rate ascribed to coronary heart disease *increased* by over 11 per cent; the coronary rate for women did not change. For American men coronary heart disease nullified much of the improvement in deaths from other causes registered since World War II. Perhaps some of this picture reflects change in diagnosis but, if so, why the difference between men and women? In any case, there is no indication that advances in diagnosis and treatment are improving the general coronary mortality picture.

TABLE 2

Death Rates, Per 100,000, Among U.S. White Persons Aged 40-59, Age Standardized

Year	Cause	Men	Women
1950	Coronary heart disease	327	78
1965	Coronary heart disease	364	77
1950	All other causes	699	493
1965	All other causes	591	400

Influencing Factors

Coronary care units are too new to have had any impact on national vital statistics, but reasonably acceptable estimates of the potential benefit can be made from information on the ordinary natural history of heart attacks and the mortality experience in special coronary units.

Coronary Care Units

Table 3 summarizes the general mortality experience with myocardial infarction in the absence of special coronary care units. Roughly one out of seven or eight patients dies suddenly, often within a few minutes of the first symptom. During the next three to four weeks, corresponding to the period of acute illness in the hospital, some 20 per cent will die. In the next eleven months the mortality adds up to become similar to that in the first hours. As a result, among persons who have a heart attack, half are dead within a year.

TABLE 3

Prognosis of Heart Attacks. (See 1963 Acta Med. Scand., Suppl. No. 406)

	Per Cent Who Die	
Period	First Attack	Recurrent
Under 2 hours	13%	15%
2 hours-4 weeks	20	22
4 weeks-1 year	13	15
One year mortality	46%	52%

Table 3 gives the picture in the absence of coronary care units. So we now ask: What happens in such units? The experience in coronary care units is that, during the period the patients are in the units, the death rate is reduced some 20 to 40 per cent below the usual experience. Accordingly, the overall effect of such units on the one-year mortality can be summed up in Table 4. The most optimistic estimate is that the one-year mortality might be reduced from 50 to 41 per cent. There is no doubt at all that some coronary patients who would die otherwise are temporarily saved by the prompt application of emergency measures in the coronary care unit. But there also can be no doubt that the provision of first-class coronary care units in every general hospital in the nation would not greatly change the total coronary mortality picture.

TABLE 4

Estimation of the Potential Life-saving Effect of Special Coronary Care Units Measured in Terms of One-Year Mortality Among 100 Persons Suffering Heart Attacks

Period	Number of Deaths	
	No Unit	With Unit
Under 2 hours	14	12*
2 hours-4 weeks	21	14
4 weeks-1 year	15	15†
	—	—
One year mortality	50	41

*Assuming more speedy admission than is now the rule.

†Assuming that patients saved from early death have as good risk as others.

From Table 4 it would appear that mortality from coronary heart disease could be reduced some 18 per cent (9/50th) by special hospital units; but this estimate neglects several considerations. In the first place, coronary patients are generally kept in special units for only four to seven days, almost never for the full four weeks of the "acute period." Therefore it is an over-estimate to suggest that the ordinary mortality rate in the period from two hours to four weeks might be cut by one third with coronary care units as they are now being used. Table 4 also assumes that mortality after discharge from a coronary care unit is the same as in the corresponding period without such units. There are no good data as yet on deaths of patients after discharge, but almost certainly their later mortality rate must be unusually high. This follows from the fact that patients discharged from the unit include some whose condition was so bad that they would have died without the resuscitation facilities of the unit. At best, then, special coronary units cannot greatly improve the one-year prognosis of a heart attack; it is possible that in the long run the mortality improvement may be negligible.

Anticoagulant Therapy

Anticoagulant therapy now seems to be almost routine for the acute period of myocardial infarction and may indeed statistically improve the immediate outlook; but at best the difference is only fractional: a heart attack is extremely dangerous with or without the availability of anticoagulant drugs in the acute period. About long-term anticoagulant therapy there is no agreement that it significantly improves prognosis. Much the same can be said about other "improvements" in the therapeutic arsenal: fibrinolytic drugs, the "polarizing" treatment, drugs to impede arrhythmias. They are interesting and in some cases may be temporarily helpful, but there is no acceptable scientific evidence that they appreciably affect the long-term prognosis of the coronary patient. This is not to decry coronary care units, new drugs and all other modern innovations, but it is necessary to emphasize that the picture of the patient who has clinical coronary heart disease remains dismal. Prevention is essential if this disease is to be brought to an acceptable level of control.

Not long ago pessimists could suggest that it is wishful thinking to talk about preventing coronary heart disease or that the price of preventing coronary heart disease would be

TABLE 5

Deaths from Coronary Heart Disease Among Cohorts of Men Aged 40-59 Followed for 5 Years. The Deaths "Expected" are Calculated from 1962 Death Rates of U.S. White Men Age-Matched by Quinquennia

Cohort	No. of Men	Number of Deaths		
		Observed	Expected	O/E
U.S. railroad men	2576	66	59.7	1.11
East Finland	814	17	17.7	0.96
Dalmatia	669	1	18.0	0.06
Crete and Corfu	1212	4	27.7	0.14

to suffer even more grievously from other diseases. Such negative views, however, cannot be maintained in the face of some recent epidemiological findings. Table 5 provides data that merit careful consideration.

Geographical Variations

The organization, samples, methods, and characteristics of men at entry examination in an international cooperative study[1] concerns individuals aged 40 to 59 who were examined in detail and then followed in regard to the development of heart disease and death. In general, the subjects include substantially *all* men of suitable age in geographically defined areas. An exception is the U.S. sample which was drawn to represent men of the appropriate age employed full time by 19 major railroad companies in the northwest sector of the United States and involved selection towards the absence of disabling disease in that all men were well enough to be employed full time. No such selection affected the men in the other cohorts reported in Table 5.

The contrasts in death rates from coronary heart disease shown in Table 5 are extreme. The U.S. railroad men and the east Finns did not differ in this respect; nor was there any significant difference between the Dalmatians and the Greeks of Crete and Corfu; but the average age-standardized coronary death rate among the U.S. men and the Finns was 9.6 times that among Greeks and Dalmatians. There were similar differences in respect to the incidence of non-fatal coronary heart disease as judged by rigid objective electrocardiographic criteria.

All deaths in this study were reviewed by non-local internists and by a common international panel. Yet the differences in Table 5 are so great as to raise questions about missed diagnoses. Suggestions about missed diagnoses of coronary heart disease are not supported by the all-causes death rate, characterized by the Greeks and Dalmatians, and as illustrated in Table 6.

TABLE 6

Deaths from All Causes Among the Cohorts of Men Represented in Table 5

Cohort	All Deaths Observed	Expected	O/E
U.S. railroad men	125	152.5	0.82
East Finland	64	45.5	1.41
Dalmatia	22	43.1	0.51
Crete and Corfu	21	39.9	0.52

These findings indicate that, somehow, coronary heart disease is promoted in some populatians, including the Finns and the U.S. men, or, conversely, the disease is prevented in other populations such as the Greeks and Dalmatians. Accordingly, it is important to ask, why?

Variable Factors

Three variables frequently proposed as being important in the etiology of coronary heart disease are considered in Table 7.

TABLE 7

Characteristics of the Cohorts of Men Whose Subsequent 5-year Mortality Was Shown in Tables 5 and 6

Cohort	Mean Relative Body Weight	% Heavy Smokers	% Relatively Sedentary
U.S. Railroad men	104	22	52
East Finland	93	31	11
Dalmatia	91	23	8
Crete and Corfu	91	27	17

Smoking Habits and Weight

These men differed little in smoking habits. The east Finns tend to be somewhat heavier smokers as measured by the number of cigarettes a day, but much of the cigarette usage in that cohort involves the Russian type of cigarette which contains much less tobacco than the usual cigarette. In relative body weight there was no significant difference among the three non-U.S. cohorts, but the U.S. men clearly tended to be much more often overweight than the other men. The frequency of excess obesity among the Americans is even more striking when body fat is estimated by measurements of the skinfolds. The average thickness of subcutaneous fat for the Americans was twice that for the other cohorts. The sedentary habits of most of the Americans undoubtedly contribute to the prevalence of obesity.

But the data in Table 7 fail to give any indication as to why the Finns should be so much more prone than the Greeks and Dalmatians to die from coronary heart disease. Being seldom sedentery and rarely obese does not seem to help these Finns who also resemble the Greeks and Dalmatians in living in the quiet countryside, mostly on their own little plots of land, free from the stresses of cities.

Serum Cholesterol and Blood Pressure

The Finns show up badly in two risk factors—serum cholesterol level and prevalence of high blood pressure (Table 8).

TABLE 8

Median Serum Cholesterol Concentration, mg/dl, and Percentage of Men with High Blood Pressure (100 or More in Diastole in Rest) in the Same Cohorts Indicated in Table 7

Cohort	Serum Cholesterol	High Blood Pressure
U.S. railroad men	236	14%
East Finland	265	21%
Dalmatia	186	8%
Crete and Corfu	201	6%

Follow-up studies on men in the United States show that the incidence of coronary heart disease among middle-aged men is increased two to three times by the presence of high blood pressure. On that basis it is interesting to estimate from the data in Table 8 the relative incidence rates that would be expected if the cohorts differed only in regard to blood pressure. With the upper estimate of a three-fold rise in incidence associated with hypertension, and taking the incidence rate in the absence of hypertension as 1.0, the expected over-all rate for the east Finns would be $3 \times 0.21 + 1 \times 0.79 = 1.42$, since 21 per cent of them were hypertensive. For the Greeks and Dalmatians the general average was 7 per cent hypertensive men; so the corresponding calculation is $3 \times 0.07 + 1 \times 0.93 = 1.14$. From these calculations the expectation would be that the incidence rate among the Finns should be $1.42 / 1.14 = 1.25$ times that among the Greeks and Dalmatians. Therefore the difference in the prevalence of hypertension between the cohorts could explain only a very small fraction of the observed difference in coronary mortality.

A similar approach can be used in regard to serum cholesterol. Follow-up studies in the U.S. indicate that the incidence of coronary heart disease among middle-aged men rises to something like the third power of the serum cholesterol concentration.[4] The general average serum cholesterol level of the Greeks and Dalmatians was about 1.95 grams of cholesterol per liter and the third power of $1.95 = 7.41$; for the Finns the average was 2.65 grams of cholesterol per liter and the third power of $2.65 = 18.61$. On this basis alone it could be suggested that the incidence rate of coronary mortality among the Finns might be $18.61 / 7.41 = 2.51$ times that among the Greeks and Dalmatians. So serum cholesterol would seem to explain far more than blood pressure in these comparisons but in itself does not account for the whole difference in the observed mortality.

Comparisons involving the U.S. men are much more complicated because they also involve great differences in physical activity and obesity. From only the characteristics of blood pressure and serum cholesterol the expectation would be that the U.S. railroad men should be intermediate in coronary mortality between the Finns on the one hand and the Greeks and Dalmatians on the other. The data suggest that obesity and lack of exercise contribute to the force of coronary mortality among the Americans. On the other hand, when all causes of mortality are considered, the differences in serum cholesterol and the prevalence of hypertension are parallel to the death rates. In any case, compared with the Americans and the Finns, coronary heart disease is largely prevented among the Greeks and Dalmatians, and it appears that a substantial but far from complete part of the explanation may lie in the serum cholesterol concentration, with blood pressure also playing a role.

In order to focus on prevention, it is necessary to proceed to another question: what are the reasons for the differences in the distributions of serum cholesterol and blood pressure? Currently there is no explanation for the blood pressure differences, no clue as to why the east Finns are three times more prone to hypertension than their counterparts in age, occupation, smoking habits, and body fatness in Greece and Dalmatia. On the other hand, the differences in serum cholesterol are not so mysterious or unexpected.

Influence of Diet

Repeated seven-day dietary surveys, including chemical analyses of the weighed food composites, were carried out on random samples of the cohorts concerned.[5,6,7] Relevant data are summarized in Table 9. Though the average diet of the U.S. railroad men, the east Finns, and the men of Crete provided almost identical percentages of total calories from total fats, the composition of the fats differed. In Finland butterfat is the dominant fat, with very little vegetable fat in the diet. In the U.S., meat fat, especially beef fat, is relatively more important, while in Crete olive oil accounts for some 80 per cent of all fat in the diet. In Dalmatia and Corfu the dietary fat is similarly dominated by olive oil. From these dietary data it would be expected that the serum cholesterol level would be higher in the east Finns than in the Americans who, in turn, would tend to have considerably higher cholesterol values than the men in Dalmatia and Greece.

TABLE 9

Average Percentage of Total Calories Provided by Total Fats and by Saturated (S) and Polyunsaturated (P) Fatty Acids in the Diets of the Men in the Cohorts Considered in Tables 5 et seq. (   )

Cohort	% Calories from:			Median Serum Cholesterol
	Fat	S	P	
East Finland	39.2	22.1	2.9	265
U. S. railroad*	40	18	6	236
Dalmatia	29.5	9.3	6.7	186
Crete	40.3	7.7	2.5	203
Corfu	32.7	5.4	3.5	198

*Chemical composition estimated from tables of food composition.

Comparison between the Finns and the Greeks is particularly interesting because their diets did not, on the average, differ significantly in the percentage of total calories provided by poly-unsaturated fatty acids. On the basis of findings in controlled dietary experiments in the United States, men on diets otherwise comparable but providing 22 versus 6 per cent of calories from saturated fatty acids would be expected to show an average difference of about 43 mg of cholesterol per deciliter of blood serum. The observed average difference was some 20 mg/dl greater, a fact that would be largely if not fully explained by greater intake of exogenous cholesterol in Finland and greater intakes of leguminous seeds, leafy vegetables and fruits in Greece.

Conclusions

This discussion has attempted to make three points. First, in the majority of cases of heart disease specific treatment has great limitations. In the American adult where coronary heart disease accounts for about three fourths of all heart disease deaths and nearly one third of *all* mortality, every consideration leads to the conclusion that prevention of coronary heart disease is essential to make any real impact on the burden of heart disease in the United States. Second, the frequency of coronary heart disease in some populations, notably in the United States and in Finland, is grossly higher than need be, as shown by studies on the incidence of the disease in some other populations. In some populations a very low incidence of coronary heart disease is associated with and productive of remarkably low all-causes mortality rates at ages 40 to 70; it is evident, then, that prevention of coronary heart disease need not lead to compensating increases in other ills. Finally, these differences in coronary heart disease among populations are associated with differences in the level of serum cholesterol and in the frequency of hypertension, risk factors that certainly can be modified by prevention programs. The differences in serum cholesterol level are largely explained by dietary differences. The conclusion is that prevention is not only essential; it is possible.

Acknowledgment

This paper makes use of a small fragment of the data, now being prepared for complete publication, collected in an international cooperative study on the epidemiology of cardiovascular disease for which the author is coordinator. That program, started in 1958, is expected to continue until about 1973. The responsible investigators of the cohorts mentioned here are: Prof. Ratko Buzina, Zagreb (the Dalmation cohort); Prof. Martti J. Karvonen, Helsinki (the east Finnish cohort); Dr. Christ Aravanis, Athens (the Crete and Corfu cohorts); Prof. Henry L. Taylor, Minneapolis (the U.S. railroad cohort). Dr. Henry Blackburn, Minneapolis, has major clinical responsibility in the overall program and Dr. Alessandro Menotti, Rome, has special responsibility for checking interim morbidity and responsibility in Europe.

Hardening of the heart ages people more quickly than hardening of the arteries.

The Evidence for Excess Risk*

in Coronary Disease

WILLIAM B. KANNEL, M.D.†
PATRICIA M. McNAMARA‡
Framingham, Massachusetts

THE NATURAL HISTORY of coronary heart disease as it arises, evolves, and terminates fatally in a general population sample has been investigated prospectively at Framingham, Massachusetts, where 5,127 men and women have been followed biennially since 1949. Since less than 2% have been lost to follow-up some valid conclusions may be drawn.[1-3] One general conclusion indicated by the findings to date is that an approach to this disease is needed which is more comprehensive than that confined to the management of the already symptomatic person. If a substantial reduction in morbidity and mortality is to be achieved it seems clear that concepts of the clinical spectrum of the disease must be broadened to include the asymptomatic phase. We must anticipate the day when a myocardial infarction occurring in a patient under medical surveillance will come to be regarded as a medical failure.

Circumstances of Myocardial Infarction

Sudden Death

Concerning survival, the critical period in a heart attack is the first few minutes. Of all deaths that occurred in initial coronary attacks in the general community more than one half were sudden and unexpected, usually unheralded by any prior symptoms. If sudden death can be included in the syndrome of myocardial infarction, then one in five cases presented with this catastrophe as the first symptom of the disease (Figure 1).

Lack of Recognition

Of all the electrocardiogram-documented infarctions that occur in a community, one in every four is unrecognized. Half of these are silent and the rest so atypical that neither the patient nor his physician even considered the possibility. As a consequence, only about 60% of coronary attacks were hospitalized in Framingham where even suspicion of an attack was cause for a hospitalization. The major reason for non-hospitalization was sudden death and unrecognized infarction. Most myocardial infarctions occur without warning in persons who believe themselves to be in good health. Only about 24% of those sustaining myocardial infarctions had prior symptoms such as angina pectoris.

†Medical Director, Heart Disease Epidemiology Study, National Institutes of Health, National Heart Institute.

‡Heart Disease Epidemiology Study, National Institutes of Health, National Heart Institute.

Stigmata of Impending Disaster

While most myocardial infarctions occurred unheralded and some never appeared above the clinical horizon, such persons were, however, seldom free of one or more stigmata which could have forecast the impending disaster. Only about 25% were free of one or more predisposing risk factors even 10 years before the attack occurred.

Deciles of Risk*

These hallmarks of unusual susceptibility have been discerned from an examination of the incidence of coronary disease in this general population classified according to antecedent personal characteristics which were believed to be important in the development of this disease. In this way a number of factors have been identified which are associated with increased risk of coronary heart disease. The details of the relationship of these factors to risk of disease have been reported elsewhere.[4-8] Using a number of these identified personal characteristics it is possible to construct, employing discriminant function analysis,[6] a coronary profile for each participant over a thirty-fold range of risks (Table 1). Risk proved to be related to the level of the major blood lipid fractions and to the coexisting blood pressure level. Blood pressure was found to accelerate lipid-induced atherogenesis, whether elevated casually or basally and whether the elevation was systolic or diastolic (Figure 2). The risk was also increased in persons with any evidence of impaired carbohydrate metabolism. Furthermore, the risk of attacks increased alarmingly in proportion to the number

of these specified atherogenic traits present, particularly the risk of fatal attacks (Figure 3). The appearance of electrocardiographic abnormalities in such highly vulnerable persons appears to predispose to an alarming rate of fatal myocardial infarctions.

The Electrocardiogram

In persons with one or more atherogenic traits, possible evidence of an impaired coronary circulation may be demonstrated even earlier by means of the post-exercise electrocardiogram. The appearance of ischemic electrocardiographic changes provoked by exercise has been convincingly demonstrated by a number of other prospective studies to be associated with a pronounced increase in risk of symptomatic coronary heart disease.[9,10] The post-exercise electrocardiogram may have more utility in detecting asymptomatic persons with a compromised coronary circulation than in clarifying the cause of atypical chest discomfort for which it is principally used today.

The appearance of electrocardiogram abnormalities at rest represents a still more advanced stage of the disease. Such occult coronary heart disease is neither rare nor innocuous. Actual myocardial infarctions as proven by serial electrocardiograms were quite common, occurring with a frequency one third as great as that of symptomatic infarctions. Discounting the immediate mortality, these apparently benign asymptomatic infarctions proved just as deadly as their symptomatically overt counterparts. Within five years one in three of either variety recurred, and in each the case fatality rate was 50% upon recurrence. Even more speculative evidence of coronary myocardial ischemia such as electrocardiographic left ventricular hypertrophy proved surprisingly serious. Such persons ran a risk of symptomatic coronary disease just about as great as persons with angina pectoris, if not equal to those with myocardial infarctions (Figure 4). The mortality in such individuals was also quite comparable to that of persons with symptomatic coronary heart disease. The appearance of this electrocardiographic finding, otherwise unexplained, even in hypertensives should suggest the onset of ischemic coronary myocardial involvement.

A.P. = M.I., C.I. OR FATAL CHD EVENT
ECG-LVH = ANY CLINICAL MANIFESTATION OF CHD

Figure 4

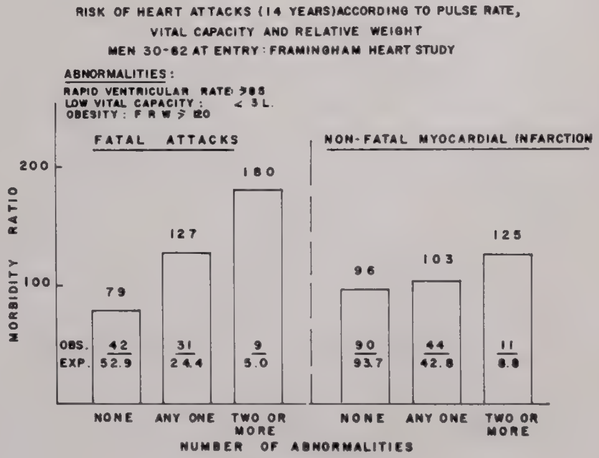

Figure 5

Pre-morbid Management

Recent innovations in the management of acute myocardial infarctions may reduce by as much as one half the deaths occurring in persons who survive long enough to reach the hospital. Selection of patients for admission to coronary care units can be difficult. Unfortunately, the absence of alarming findings on admission is no guarantee against a sudden fatal termination to the illness. Criteria for the selection of such persons requiring management in a coronary care unit may be derived from a study of pre-morbid factors associated with a lethal outcome.

Age

The case fatality rate generally increases with age, but at each age some persons may be identified who are distinctly more vulnerable to a fatal outcome than others. Persons with a prior myocardial infarction and those with electrocardiographic abnormalities such as left ventricular hypertrophy and intraventricular block have a case fatality rate which approaches 50%. Also the case fatality rate increases in proportion to the number of prior atherogenic traits present. Persons with certain possibly sedentary traits such as a low vital capacity, a rapid resting pulse rate and obesity are especially likely to have a fatal attack (Figure 5). It would seem that patients with a combination of atherogenic traits, those with electrocardiographic abnormalities, and those with sedentary attributes are candidates for special coronary care unit management regardless of their clinical condition on admission.

Should the patient survive the initial attack, his troubles are far from over. Most heart attack victims who are free of angina and congestive failure before the attack will continue free of it, and only about 27% will develop angina pectoris they did not have before. Most will be able to return to their usual occupation. The principal hazard lies not in disabling symptoms but in the likelihood of another attack. Depending on age, this relative risk may be five to ten times that of their cohorts free of symptoms of coronary heart disease. As indicated in Figure 4, the absolute risk in men 45 to 62 appears to be in the neighborhood of 50% within eight years. These people also have at least a threefold increased risk of a stroke to add to their burden. Even though asymptomatic, such individuals are in dire need of secondary prevention designed to delay recurrences.

Elimination of Cigarettes

In such susceptible people certain modifications in living habits would seem prudent. The cigarette habit appears to be distinctly pernicious in predisposing to recurrences with fatal outcome. This was true even for persons whose only evidence of ischemic myocardial involvement was asymptomatic electrocardiographic findings (Figure 6). There is much to be gained in giving up the habit since the effects seem to be transient, non-cumulative, and apparently reversible. The risk is related to the number of cigarettes smoked each day, but not to the duration of the habit, so that those who give up the habit seem rapidly to revert to a better risk status.[11,12]

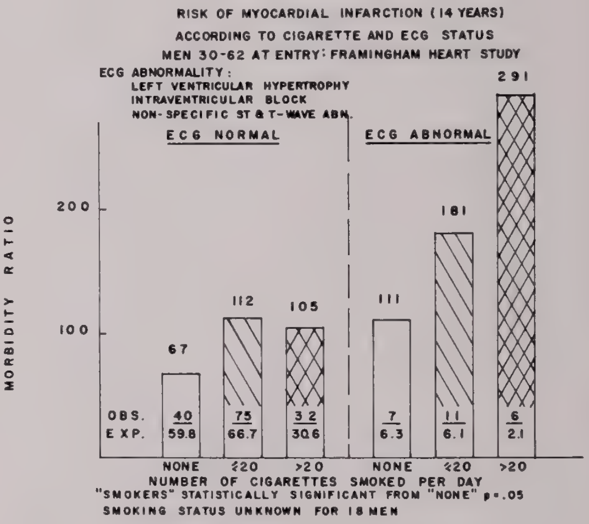

Figure 6

Sloth and Gluttony

Obesity, or the habits of sloth and gluttony which lead to obesity, are apt to bring on angina pectoris and to result in an unusual propensity to sudden death. This was particularly true in those who had predisposing atherogenic traits and, perhaps as a consequence, a compromised coronary circulation (Figure 7).

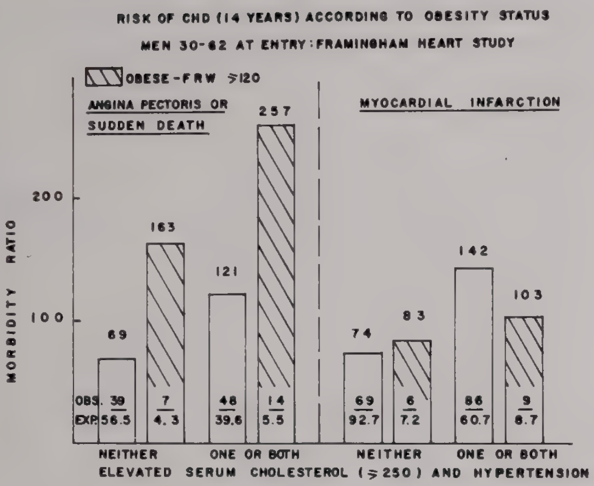

Figure 7

Supervised Exercise

Severe restriction of activity in recovered myocardial infarction victims or in those who are highly vulnerable to it may be unwise, since the sedentary seem to develop an excess of fatal attacks. Promotion of collateral circulation by supervised exercise may afford some protection against a lethal outcome when an occlusion has already occurred.

Conclusions

From an examination of the natural history of coronary heart disease it is apparent that a preventive approach is essential. The measures required are indicated by the factors demonstrated to be associated with an increased risk of attacks and of lethal outcome. While research is urgently needed to demonstrate the efficacy of the preventive measures which seem indicated, the problem is really too serious to permit much temporizing. This is a very common and a very highly lethal disease.

In a ten-year period in Framingham, one in every 10 men and one in every 20 women developed it. The men developed more disease earlier in life and in a more severe form. Evidence has been presented, however, that the disease is not an inevitable consequence of aging or genetic makeup, for at any age in either sex some were identified who were distinctly more vulnerable than others. Such highly susceptible persons can be readily identified by the physician and efforts instituted in an effort to delay attacks.

The general hygienic measures indicated are not easy to implement. Both the physician and the patient would prefer a pill to counteract bad habits. However, the potential for salvage of such vulnerable persons is huge and well worth the effort, whether pharmacologic or hygienic. More effective means for implementing preventive programs which include alteration in diet, maintenance of physical fitness, exercise programs, weight reduction, discontinuing the cigarette habit, and early control of abnormal blood lipids, hypertension and impaired carbohydrate metabolism, are urgently needed. Both the physician and his patient will require considerable assistance in their collaborative effort to achieve these goals.

Old Hospitals

Hospital of the Holy Spirit, Rome

In medieval Europe, poverty was widespread and social welfare agencies, largely in the hands of the Church, were few. To provide for the sick poor of the city of Rome, Pope Innocent III directed the building of this hospital between the years 1198 and 1201. The Pope brought the newly-founded Order of the Holy Spirit from Paris to operate the hospital under the direction of its founder, Guy de Montpellier. The hospital, in a 13th-century city of hardly 35,000, had a bed capacity of 300 and served 1,000 people per day in what might be called its outpatient department.

The institution became a complete welfare center, operating a maternity home, a nursery, an orphanage, a geriatric nursing home, and a kind of rehabilitation center. It was the first teaching hospital in Rome and has been a center for medical research since the days of Leonardo da Vinci. In the 16th century, its pharmacy played an important part in the distribution of chinchona.

The building shown in this picture was erected in 1478, and is still occupied by patients. Its interior consists of two huge high-ceilinged wards lined with hospital beds. Old frescoes and paintings adorn the walls, and there is a sanctuary and altar between the wards. Under the dome is the hospital board room and a famous library of history of medicine. The hospital is located only a few blocks from the Vatican in the district called Sassia.

Overweight

Gourmand: a man who dies an early death from being overweight.

an antibiotic you can use without risk to the kidney

Polycillin-N®

(sodium ampicillin)

the penicillin you use like a broad-spectrum antibiotic

PRESCRIBING INFORMATION. 11—1/2/69. For complete information consult Official Package Circular.

Indications: Infections due to susceptible strains of Gram-negative bacteria (including Shigellae, *S. typhosa* and other Salmonellae, *E. coli, H. influenzae, P. mirabilis, N. gonorrhoeae* and *N. meningitidis*) and Gram-positive bacteria (including streptococci, pneumococci and nonpenicillinase-producing staphylococci).

Contraindications: A history of allergic reactions to penicillins or cephalosporins and infections due to penicillinase-producing organisms.

Precautions: Typical penicillin-allergic reactions may occur, especially in hypersensitive patients. Mycotic or bacterial superinfections may occur. Experience in newborn and premature infants is limited and caution should be used in treatment, with frequent organ function evaluations. Safety for use in pregnancy is not established. In gonorrheal therapy, serologic tests for syphilis should be performed initially and monthly for 4 months. Assess renal, hepatic and hematopoietic function intermittently during long-term therapy.

Adverse Reactions: Skin rash, pruritus, urticaria, nausea, vomiting, diarrhea and anaphylactic reactions. Mild transient elevations of SGOT or SGPT have been noted. Black tongue has been noted in some patients receiving the Chewable Tablets.

Usual Dosage: Adults—250 or 500 mg. q. 6 h. (according to infection site and offending organisms). Children—50-100 mg./Kg./day in 3 to 4 divided doses (depending on infection site and offending organisms). Bacterial meningitis—150-200 mg./Kg./day in 6 to 8 divided doses. Children weighing more than 20 Kg. should be given an adult dose when prescribing orally. In parenteral administration, children weighing more than 40 Kg. should be given an adult dose. Beta-hemolytic streptococcal infections should be treated for at least 10 days.

Supplied: Capsules—250 mg. in bottles of 24 and 100. 500 mg. in bottles of 16 and 100. For Oral Suspension—125 mg./5 ml. in 60, 80 and 150 ml. bottles. 250 mg./5 ml. in 80 and 150 ml. bottles. Chewable Tablets—125 mg. in bottles of 40. Injectable—for I.M./I.V. use—vials of 125 mg., 250 mg., 500 mg., and 1 Gm. Pediatric Drops—100 mg./ml. in 20 ml. bottles.

BRISTOL

BRISTOL LABORATORIES
Division of Bristol-Myers Company
Syracuse, New York 13201

Indications: For the treatment of trichomoniasis in both male and female patients and the sexual partners of patients with a recurrence of the infection provided trichomonads have been demonstrated by wet smear or culture.
Contraindications: Evidence of or a history of blood dyscrasia, in patients with active organic disease of the central nervous system, and the first trimester of pregnancy.
Warnings: Use with discretion during the second and third trimesters of pregnancy and restrict to patients not cured by topical measures. Flagyl (metronidazole) is secreted in the breast milk of nursing mothers; it is not known whether this can be injurious to the newborn.
Precautions: Mild leukopenia has been reported during Flagyl use; total and differential leukocyte counts are recommended before and after treatment with the drug, especially if a second course is necessary. Avoid alcoholic beverages during Flagyl therapy because abdominal cramps, vomiting and flushing may occur. Discontinue Flagyl promptly if abnormal neurologic signs occur. There is no accepted proof that Flagyl is effective against other organisms and it should not be used in the treatment of other conditions. Exacerbation of moniliasis may occur.
Adverse Reactions: Nausea, headache, anorexia, vomiting, diarrhea, epigastric distress, abdominal cramping, constipation, a metallic, sharp and unpleasant taste, furry or sore tongue, glossitis and stomatitis possibly associated with a sudden overgrowth of *Monilia,* exacerbation of vaginal moniliasis, an occasional reversible moderate leukopenia, dizziness, vertigo, drowsiness, incoordination and ataxia, numbness or paresthesia of an extremity, fleeting joint pains, confusion, irritability, depression, insomnia, mild erythematous eruptions, "weak-

Flagyl®

brand of

metronidazole

simplifies vaginitis therapy

The effectiveness of Flagyl in *Trichomonas vaginalis* vaginitis has been so constant that use of less effective agents would seem to invite unnecessary failures. ▪ The simplicity, completeness and persistence of cures with Flagyl qualify it as the logical first therapeutic choice in trichomonal infections.

simple Ten-day treatment with Flagyl oral tablets has replaced a multitude of untidy douches, powders, creams and jellies.

complete Flagyl is the only medication available that is able to reach all the crypts, glands and cavities of the female urogenital system as well as reservoirs of reinfection in male trichomonas carriers.

lasting Flagyl eradicates resistant, deep-seated invasions of *Trichomonas vaginalis* and consistently produces cure rates above 90 per cent and often as high as 100 per cent in large series of patients. When the diagnosis is positive, Flagyl is positive.

ness," urticaria, flushing, dryness of the mouth, vagina or vulva, vaginal burning, pruritus, dysuria, cystitis, a sense of pelvic pressure, dyspareunia, fever, polyuria, incontinence, decrease of libido, nasal congestion, proctitis, pyuria and darkened urine have occurred in patients receiving the drug. Patients receiving Flagyl may experience abdominal distress, nausea, vomiting or headache if alcoholic beverages are consumed. The taste of alcoholic beverages may also be modified.

Dosage and Administration: In the Female. One 250-mg. tablet orally three times daily for ten days. Courses may be repeated if required in especially stubborn cases; in such patients an interval of four to six weeks between courses and total and differential leukocyte counts before, during and after treatment are recommended. Vaginal inserts of 500 mg. are available for use, particularly in stubborn cases. *When the vaginal inserts are used,* one 500-mg. insert is placed high in the vaginal vault each day for ten days and the *oral dosage is reduced to two 250-mg. tablets daily during the ten-day course of treatment.* Do not use the vaginal inserts as the *sole* form of therapy. *In the Male.* Prescribe Flagyl only when trichomonads are demonstrated in the urogenital tract, one 250-mg. tablet two times daily for ten days. Flagyl should be taken by both partners over the same ten-day period when it is prescribed for the male in conjunction with the treatment of his female partner.

Dosage Forms: Oral tablets .....250 mg.
Vaginal inserts ...500 mg.

Prevention of Coronary Disease

ROCHESTER, MINNESOTA, was the scene of a significant symposium conducted in May of 1968 on the subject of the prevention of coronary disease. Doctor Henry Blackburn, the chairman, assembled the papers on the subject presented there and now appearing in this issue of MINNESOTA MEDICINE.

Paul White (The Challenge of Prevention) reviews the history of cardiology in his lifetime which encompasses the modern era. He points out that successful prevention of infectious heart disease, especially rheumatic disease, leaves coronary disease the supreme killer and almost untouched preventatively. Jeremiah Stamler (Reducing Cardiovascular Risk) describes the need for preventive efforts against heart disease in this country. He believes that not more than 10 per cent of hypertensive patients are receiving adequate care. Data from the Coronary Drug Project of which he is chairman show that 50% of males who have had one or more myocardial infarctions are still smoking. The medical profession is overwhelmed by the need for treatment of overt disease and has no time for prophylaxis.

Kannel and McNamara (The Evidence for Excess Risk) in the Framingham Study emphasize the need to investigate asymptomatic disease. One in ten men and one in twenty women in this study developed evidence of coronary disease over a ten-year period. The disease, however, is not the inevitable consequence of aging since at all ages and in both sexes highly susceptible individuals can be identified. They should be intensively treated with regulation of diet, weight, physical activity, smoking, lipid and carbohydrate metabolism, and blood pressure. Dawber (Identification of Excess Cardiovascular Risk) from the same group includes also gout, xanthomatosis, hypothyroidism, and variations of hemoglobin either high or low whose correction may be prophylactic against coronary disease.

Hellerstein (The Effects of Physical Activity) chastises the sedentary, lazy, overweight, hypertensive, smoking, cholesterolemic male for these characteristics. His conditioning program has resulted in improvement that is essentially psychological. He believes a reconditioning program should be prescribed for, among others, "normal" but coronary-prone men.

Nunn et al. (a Lipid Clinic) at the Mayo Clinic have collected 100 hyperlipidemic patients in less than two years. The authors divide them into two lipid populations about half Type II with normal triglycerides and hypercholesterolemia which can be reduced with diet and cholestyramine; and the rest Types II, III, and IV with elevated triglycerides which they treat with diet and clofibrate. Ancel Keys (The Essentiality of Prevention) continues his discussion of the great differences

WHEN YOU WANT COUNSEL—
YOU WANT THE BEST!

That's why we're proud to publicize our twenty-four years of experience working exclusively with the Medical and Dental Professions. Consider also the 50 Consultants and 2000 Clients involved and you know that within the framework of our organization must lie the answer to your problems, whatever they may be. We offer you wide experience, vast statistical data, and expert counsel on all phases of practice management and personal financial planning—RECORDS, ROUTINES, TAXES, INVESTMENTS, INSURANCE, CREDIT AND COLLECTIONS, FEES, PERSONNEL, PARTNERSHIP PROBLEMS, AND MORE.

Our representative in your area will be pleased to explain to you—without obligation—how you, too, may have at your disposal all that the past twenty-four years have taught us. Surely it's worth your time to investigate!

Physical Activity and the Cardiac Patient

REGULAR PHYSICAL activity in moderation is almost universally considered of psychologic benefit to the participant. Physiologic and metabolic benefits may also be derived, depending on the form and energy-expenditure requirements of the activity. Dr. Oglesby Paul* has pointed out the difficulties in evaluating epidemiologic, pathologic, and physiologic data relating to the role of exercise in coronary atherosclerosis.

Thus far the most objective physiologic response in cardiac patients after a regular exercise program includes a significant reduction in the resting pulse rate, a decrease in the systolic and diastolic blood pressures both at rest and while expending energy, and a significant increase in physical working capacity. The development of collateral coronary artery circulation secondary to increased physical activity has not been studied to the extent that any conclusion can be reached.

Only partial studies of metabolic parameters have been made. Evidence that regular exercise influences cholesterol or triglyceride levels is not conclusive. However, it has been our observation that participants in a program of supervised exercise are better motivated to adhere to a weight-reduction program, and lipid levels subsequently decrease. In a small group of nine patients studied after four to six weeks of exercise, serum lactate levels were lowered.[1]

The psychologic response of cardiac patients to a supervised graduated exercise program is gratifying. Many patients have tailored their physical activities to avoid the annoyance of angina prior to participation. When some degree of physical training has been achieved they become more assertive, hopeful, and occasionally euphoric to a degree that limits must be placed on their physical activity.

The effect of regular exercise on morbidity and mortality has not been satisfactorily discerned but it does seem to be a definite asset in rehabilitating the patient who has angina or who has had a myocardial infarction.

The Elusive Treatment of Angina

William Heberden introduced the term, angina pectoris, in the mid-eighteenth century,[1] but descriptions of this malady have been noted dating back centuries before his scholarly account of its clinical manifestations. From ancient times to the present, physicians have attempted a variety of therapeutic measures to counter this serious condition; recent years have found medical literature replete with new treatments and modifications of the old. The only specific medication for the relief of angina pectoris to date is the nitrite group of drugs and their exact mode of action continues to be controversial. Nitroglycerin was first introduced scarcely ten years after Heberden's classic description.[2] The intervening years have been both fruitful (considering the large quantity of reseach that has been performed with resultant ancillary benefits) and frustrating (in that a more effective regimen has defied recognition and general acceptance). Psychotherapy, thyroid ablation, anticoagulants, mammary artery ligation, alcohol and physiotherapy are just some of the widely divergent modes of treatment that have met with apparent initial success in recent years. It is safe to assume that none of these measures has thus far stood the test of time as an effective therapy which is relatively free of complications. The same cannot be said at this point for arterial-myocardial diversion (Vineberg) procedures, beta adrenergic blockade or carotid sinus nerve stimulation.

Information continues to increase concerning these three methods. An example of this is found in the paper by Brinkman and Alexander* which appeared in the May issue and was devoted to the clinical experience with propranolol at the Minneapolis Veterans Hospital. The majority of the clinical research with this drug alone and in combination with nitrites has been encouraging since clinical investigation with it was instituted in 1964. Their paper seems to continue this trend. However, as recently as April, 1969, Aranow and Kaplan, in a controlled double-blind study using a combination of propranolol and isosorbide dinitrate, found the following: 30 percent of their experimental patients had fewer anginal episodes while on the drugs, and 44 percent of the control placebo group had fewer anginal episodes.[3] They also noted an apparent superiority of the placebo over the drug combination in exercise performance by a factor of three to four-fold and thereby provoked the question: Are the negative inotropic and chronotropic effects of propranolol, which constitute the physiologic basis for the hoped for reduction in angina, acting as a "double edged-sword" by ultimately increasing myocardial oxygen demand and consumption? Most reports[4,5] are at variance with Aranow and Kaplan and their earlier study using propranolol and isosorbide dinitrate singly and in combination (no statistical difference between treatment and placebo groups),[6] but their paper is most certainly "food for thought."

No clear-cut answer to this elusive problem is apparent, and controversy still rages in discusions of the Vineberg procedure and carotid sinus nerve stimulation as well as beta adrenergic blockade. It has long been recognized that the discomfort so adequately chronicled by Heberden is dependent upon many environmental stimuli and individual variations; one wonders: Could it not be the "subjective nature of the beast" that thwarts our endeavors to efficiently do battle with it?

Complications of Cardiac Catheterization and Angiography

THE COMPLICATIONS reported by Doctor Hook* are familiar to those working in the field of cardiac catheterization and angiography and emphasize the hazards in these procedures. As the author points out, the benefits of these procedures well justify the risk involved in properly selected cases.

For a cardiac catheterization laboratory to function successfully in a community general hospital several requirements must be met. The laboratory should be under the direction of a cardiologist with experience in performing the various procedures and in evaluating and selecting the patients to be studied. The cooperation of the radiologist is important to obtain the maximum benefit from the procedures. A cardiovascular surgeon should be available in the hospital to aid in the management of the occasional complication and also to participate in the function of the laboratory. Adequate technical help often means the difference between a successfully and a poorly functioning laboratory.

As in other areas of medicine, the successful function of a cardiac catheterization laboratory depends on close cooperation between all of the individuals involved. With properly trained individuals and support from the hospital board, there is no reason why these studies cannot be performed in community hospitals.

The Editor's Soliloquy

The "In-Thing" To Do

"YOU MUST BE a professor, correcting all those papers," was the introductory remark of a young college sophomore who stopped by to pass the time of day. We were in the Vistadome of the Great Northern "Empire Builder" as I was on my way home from a medical search-out.

I had been musing on the baffling paradoxes that belie the adjective *sapiens* in man's proud arrogation of the term *Homo sapiens*: So far as I am aware, no other animal persists so consistently and conspicuously in behaving in his own worst interest: smoking, over-eating, excessive drinking, and inadequate exercise. Weren't cigarettes long ago termed "coffin nails" —long before any remote linkage with lung cancer was suspected? Yet now, with all their notoriety as carcinogenic agents, has not their consumption increased in alarming proportion to the population? The reason I suspect is their glamorization.

"No," I was merely doing a bit of editing of manuscripts for our medical journal: exposing the hazards to the cardiovascular system to which millions of people deliberately, sometimes defiantly, sometimes cavalierly, expose themselves by their excesses.

I was startled but pleased by the student's interruption of my reverie, subsequently even more pleasantly surprised when the young man informed me that at his school, Malta High School, Montana, most of the students, both boys and girls, had renounced the habit of smoking. In a total of 350 registrants, he further announced, there were only five or six hold-outs. That sounded incredible! And if he knew the secret of its accomplishment the American Cancer Society should surely hear about it!

The student body had voted to discuss the question: to smoke or not to smoke; a few simple scientific facts were brought out; medical research was cited; the sensuous and psychic pleasures of cigarette smoking were assessed and objectively weighed against the health hazards. A few influential students expressed their mature opposition to the pernicious habit; emotion and sentiment were disavowed; families' wishes and crusaders' exhortations were dismissed as irrelevant! No rewards would be forthcoming; no pledges or promises solicited! Emotional outbursts were repudiated as immature and in poor taste.

The student body registered the majority opinion that the "in-thing" to do, if offered a cigarette, was to say simply: "No, thank you"—with no ifs, ands or buts; no explanations, no apologies, no holier-than-thou implications.

"Have a cigarette?"

"No, thank you."

Identification of Excess Cardiovascular Risk*

A Practical Approach

THOMAS R. DAWBER, M.D.†
Boston, Massachusetts

FOLLOWING THE RESULTS of research which suggests merit in new diagnostic, therapeutic or preventive procedures in medicine, there is a period of uncertainty during which a clarification of the practical usefulness of the procedures takes place. Some procedures can be adopted directly; others require considerable modification, and some turn out to be impracticable.

The demonstration, primarily through epidemiologic investigations, that certain constitutional and environmental characteristics are related to the development of coronary heart disease has brought about exploration into methods of favorably changing these characteristics. Moreover, studies have been undertaken to determine whether changing them is effective in reducing the risk of coronary heart disease development. In most instances the results are still inconclusive because of insufficient numbers of subjects observed over inadequate time.

Critics challenge the role which various risk factors play in the development of the disease. Others accept their role but doubt that effective means of changing them are available or acceptable to medical consumers. Others question whether "proof" of any benefit from changing the "risk factors" has been established. Most admit that the relative importance of various risk factors so far identified needs elaboration, and that unidentified risk characteristics, such as those related to hypercoagulability, must be sought. Though the methods for changing risk characteristics are far from perfect, and the evidence of benefit from change still has to be obtained, reasonable physicians act in accordance with the maxim of Dr. Samuel Johnson that "Nothing will ever be attempted if all possible objections must first be overcome." They wish to identify persons at unusual risk and to attempt the indicated changes, anticipating a beneficial result.

---

*Presented at the Minnesota Symposium on Prevention in Cardiology, May 2-3, 1968 in Rochester, Minnesota.

†Associate Professor of Medicine, Boston University Medical Center.

Usefulness of Preventive Measures

The acceptability by physicians of the usefulness of a procedure is not always based on factual evidence. For example, physicians continue to accept, and in fact strongly advocate, surgery for certain types of malignant tumors in spite of weighty evidence that this form of treatment is not really effective. The surgical removal of tumors *seems* a rational treatment, and once a form of therapy becomes common practice it is usually accepted uncritically for a long time.

At present it appears reasonable to advocate changes in risk factors, even in the absence of complete evidence of the value of such procedures. Meanwhile, research into the benefit of changing risk factors, the degree of change required, the best methods of making the changes, the ages of the population at risk when changes would be most effective, etc. should be top priority in medical research.

Physicians who accept the usefulness of preventive measures in coronary heart disease must make certain decisions regarding which individuals are at sufficient risk to warrant an attempt being made to mitigate that risk.

Examples of questions to be answered are the following:

1. What populations should be selected for risk factor modification?
2. Which tests are both useful and practicable for the M.D. to use in his office?
3. At what point does the risk become sufficiently great to warrant medical interference.

The answers to these questions are relative rather than absolute and require individual judgment. General guidelines have been developed by the American Heart Association and published in its statement on Risk Factors and Coronary Heart Disease (1968).

Selection of the Population at Risk

It is first necessary to consider groups in which the risk of subsequent coronary heart disease is sufficiently high to warrant attempted modification. The general population at highest risk of coronary heart disease development can be divided into three major categories. Some comments about these groups are in order.

Overt Disease

Recognized

Recent studies have suggested that persons with known myocardial infarctions can decrease their recurrence rate by judicious prophylactic procedures. Since those who already present evidence of disease are at the top of the list of risk for future serious heart attacks, it seems wise to bring them under medical supervision. These include persons with known angina pectoris, coronary insufficiency and myocardial infarction who require investigation to find defects which may be partially responsible and which can be changed (e.g., blood pressure, lipid abnormality).

Unrecognized

About 25% of all cases of myocardial infarction are unrecognized. These can be detected only by routine electrocardiographic tracings recorded as part of an examination of all men over age 40 and all women over age 50. This procedure should be made a part of community screening programs and of detection in the physician's office. In community programs it is possible to screen large numbers of persons in a short time. The diagnosis of angina pectoris in doubtful cases can be confirmed by the performance of an exercise test, such as a step test. This is also practicable for use in the physician's office. Asymptomatic myocardial ischemia (asymptomatic electrocardiogic changes brought on by exercise) can also be detected in a fraction of the apparently well population. This approach, however, appears to have a doubtful place in screening other than to assist in the differential diagnosis of chest pain of undetermined nature.

Recognizable Diseases Associated with Coronary Heart Disease

Xanthomatosis

This familial disorder is almost always associated with hypercholesterolemia. In addition, coronary heart disease is quite common, often occurring at a very early age. The presence of xanthomatosis, whether tendinous, tuberous, or eruptive, calls for detailed lipid studies, i.e., serum cholesterol, triglycerides and electrophoretic* patterns.

In addition to xanthomata, xanthelasma also may be evidence of an abnormality of cholesterol metabolism. Approximately 50% of persons with xanthelasma will have elevated serum cholesterol levels. Xanthomatosis itself is very rare in the general population; xanthelasmata are much more common.

Diabetes Mellitus

The increased risk of coronary heart disease in subjects with diabetes mellitus makes it worthwhile to try to detect this disease, even in a "mild" state. As a routine procedure, determination of blood sugar three hours after a meal of moderate carbohydrate intake is recommended. When it is not possible to impose a fixed time interval following a meal, casual blood sugars with notations regarding the time since eating, and the composition of the meal, will suffice. In this situation, if elevated blood sugar levels are detected, retesting is necessary with a three-hour postprandial blood sugar determination. Occasionally, a complete glucose tolerance test may be indicated. When the physician makes a diagnosis of diabetes, even of minimal severity, he should make a detailed evaluation of the serum lipids.

The continued high rate of coronary heart disease in diabetics who are under "good" medical management for their carbohydrate metabolic defect suggests that current diabetic therapy is insufficient and that careful attention should also be paid to correcting the lipid abnormality.

Gout

Since an elevated blood uric acid level predisposes to both gout and coronary heart disease, the serum uric acid should be estimated in men with a history of gout or other joint disorder.

Hypothyroidism

Though hypothyroidism with associated hypercholesterolemia may predispose to coronary heart disease, data from the Framingham Study suggest that neither hyper- nor hypothyroidism is sufficiently common in the general population to warrant a screening protein-bound iodine determination unless there is reason to suspect thyroid metabolic abnormality. Anyone with symptoms suggesting hypothyroidism should have careful evaluation of his thyroid state.

No Recognizable Disease but Measurable Risk

In the remaining "well" population with neither overt coronary heart disease nor evidence of any other definable disease, it is desirable to identify those persons at sufficiently high risk to warrant intervention. Distinction between those with "disease" and those without disease as discussed above is relatively sharp. No such sharp distinction, however, can be made between those with risk factors and those without. Rather, the physician must decide at what point on a continuous curve the risk is high enough to warrant the effort required to lower the risk.

In its statement on Risk Factors and Coronary Disease, the American Heart Association recommends that "individuals with a twofold or more increase in risk be referred to physicians for prophylactic management." Individuals with any of the following findings fit into this level of risk.

Serum Lipids

There is little doubt that certain abnormalities of lipid metabolism are related to the development of coronary heart disease. This includes certain recognizable familial diseases. Other acquired diseases which present evidence of lipid abnormalities, e.g., biliary cirrhosis and nephrosis, have not been related to coronary heart disease development, but this is probably because the diminished life span of the intrinsic disease precludes a study of this relationship. Lipid tests include:

Inspection of blood serum (or plasma) for turbidity. If the serum is clear, the presumption is that the triglyceride levels are not elevated. But absence of turbidity is not proof that such elevation does not exist. Cloudiness of serum, however, may be the result of alimentary hyperlipemia, and serum must be inspected after at least 12 hours of fasting. If still turbid, a presumption of elevated triglycerides is made.

---

*See Test Your Word Score Page 1213.

In any case, determination of total serum cholesterol is required. If the cholesterol level is not elevated (see Risk Factor Statement of American Heart Association) and the fasting serum is clear, no further study of blood lipids is required. If the serum is cloudy, determination of the triglycerides is warranted. Electrophoretic lipid patterns are rarely needed, if cholesterol and triglyceride determinations are available.

Determination of total serum cholesterol is sufficient both for screening purposes and for routine check-up examinations in the absence of possible lipid metabolic disease (known coronary heart disease, family history of coronary heart disease, evidence of gout, etc.).

The impression has been created that carbohydrate-induced hyperlipidemia is the only important lipidemia related to atherosclerotic disease. Too much emphasis has been placed on this entity in view of its relatively slight contribution to atherosclerotic disease.

If diabetes is detected by determination of carbohydrate metabolic defects, there is little reason to measure other lipids than total serum cholesterol, among the general population. The evidence still points to the level of serum cholesterol as the most important lipid measurement to consider in the screening and prediction of coronary heart disease.

Blood Pressure

The importance of elevated blood pressure in the production of coronary heart disease is generally accepted. Experts debate the relative merits of the measurement of casual versus basal blood pressure, the importance of fixed versus labile pressure, and of systolic pressure versus diastolic. Important to the practicing physician is the predictive value of the casual pressure which can be taken in his office. Clearly blood pressure is a variable characteristic and in general is more variable the higher the level.

Studies in Framingham have clearly established that classification of subjects on the basis of the initial casual blood pressure measurement agrees well with a similar classification using the mean of a series of such measurements over time. However, the physician must determine the blood pressure in the same way in all patients if he is to attach importance to the casual measurement. For screening purposes, the evidence indicates that the initial casual blood pressure suffices. In order to decide what to do about a particular blood pressure level, the physician may wish to determine the mean value of a series of blood pressures. Nurses' and technicians' readings are generally lower than physicians'.

Hemoglobin or Hematocrit

In view of the increased rate of coronary heart disease and stroke at both low and high levels of hemoglobin and hematocrit, the determination of either of these measurements appears desirable in screening procedures in the community and in office practice. Simple devices for hematocrit determination are readily available and practicable.

Vital Capacity

A relationship between vital capacity and risk of subsequent coronary heart disease has been demonstrated in the Framingham data. The better the vital capacity, the lower the risk. A number of associations can be found between vital capacity and other measurements, such as height, which in turn are also related to coronary heart disease risk. Vital capacity is probably a resultant of a number of factors including physical activity and body build. The recording of a timed vital capacity provides a permanent record for future comparison, when a decrease in vital capacity may signal impending congestive failure or when changes in the pattern may signal emphysema or obstructive bronchopulmonary disease.

Physical Strength

At the present time there is insufficient evidence that degrees of physical activity are important in contributing to the morbidity rate of coronary heart disease. However, people who are more physically active are more likely to survive heart attacks once they have occurred. Some measure of "physical activity" is desirable for classifying subjects, and in calling attention to lack of "physical fitness." A proper assessment might involve a number of muscle-testing procedures but is not practicable. Limited measurements, such as hand-grip strength, are of some value and can be included in a battery of tests with little expenditure of time.

Weight and Fat Measurement

Weight measurement is routine in most physicians' offices. The absolute degree of over- or underweight or the percentage by which the individual is over- or underweight must then be determined.

But how much of the excess weight is undesirable fat? Elaborate techniques must usually be employed for the latter. Simple weight-for-height, compared to standard tables, may be satisfactory. Additional measurements of fat using calipers may also be used.

Present evidence suggests that it is primarily those with considerable excess weight who have an increased risk of coronary heart disease development. Data from Framingham indicate that a degree of overweight which is 30% or more above that expected can definitely be labelled a risk factor.

Summary

Many epidemiologic studies have demonstrated that certain host and environmental factors are clearly related to a high risk of development of subsequent coronary heart disease. These characteristics may be grouped into three categories:

(1) Those persons already presenting evidence of existing coronary heart disease, much of which may be subclinical.

The inclusion of an electrocardiographic examination in the routine physical examination of all adults will disclose almost all subclinical coronary heart disease. Persons presenting with chest or related pain of undetermined etiology may require exercise electrocardiograms.

(2) Those persons with certain other diseases which clearly predispose to early coronary heart disease.

Included are xanthomatosis and familial hypercholesterolemia, diabetes mellitus, gout, and hypothyroidism. Persons with these diseases should be considered candidates for early development of coronary heart disease. They should have careful evaluation of blood lipids, blood pressure and other risk factors mentioned below.

(3) Apparently well people in whom certain findings are present which increase the risk of coronary heart disease development.

In this well population the following factors should be looked for and can be measured by the practicing physician in his office or in a community detection program.

Conclusions

In almost all instances the measurement of total serum cholesterol is all that is required.

Casual blood pressure as measured by the practicing physician is adequate for detection purposes. The physician faced with a decision as to whether treatment is indicated and the type of treatment to be selected may require more elaborate investigation.

Weight for the individual's height group compared to standard tables will allow the patient to be classified in terms of relative weight. Persons who are 30 per cent or more above weight are at a definitely increased risk of coronary heart disease development.

Measurements of physical fitness are relatively crude. Vital capacity and measurement of hand-grip strength will give some suggestion of physical fitness.

Elevation of these measurements increases the risk of thrombotic disorders. Inclusion of these measurements is therefore indicated in any screening program or office evaluation.

Man

There are three classes of men in the United States—the intellectual, the handsome, and the majority.—Construction Digest.

The power imprisoned in the atom is not greater than the power imprisoned in the human soul.—Forbes Epigrams

Nobel Prize Winners in Medicine and Physiology

Christiaan Eijkman 1929

For his Discovery of the Antineuritic Vitamin

"An accident set me on the right road.

"In the chicken-run of the laboratory in Batavia there suddenly broke out a disease which was in many ways strikingly similar to human beri-beri, and hence invited penetrating study.

"As may already be guessed from the symptoms (unsteady gait, muscular weakness, collapse, progressive paralysis, cyanosis, or blueness of comb and skin, stupor, subnormal temperature, and death) and the course of the disease, and as microscopic study confirmed, it was a question of a polyneuritis.

"As regards etiology . . . search for infection, using materials from sick animals or those that had died of the disease, gave no clear result, while all the hens, including those kept separate as controls, were affected. No specific microbe was found, nor any higher organized parasite.

"Then all at once our opportunity for further researches disappeared, as the disease came suddenly to a stop. The sick hens got better and no new cases appeared. Fortunately suspicion was then directed toward food.

"The laboratory was still temporary, and very meagerly housed in the military hospital, although it was administered under the civil authority. The laboratory attendant, his motive economy, had now, as I first learned later, obtained cooking rice from the hospital kitchen to use as chicken-feed. Then, the cook having been transferred, his successor objected to military rice going to civilian hens. So it happened that the hens were fed with cooking rice only from the 10th of June to the 20th of November. But the epizootic began on the 10th of July and ended in the last days of November.

"Deliberate feeding experimentation was then undertaken. This definitely showed that the polyneuritis had its origin in the cooking-rice feed. The hens were thereby subjected to the disease after 3-4 weeks, while the controls fed with unhulled rice remained healthy.

"This rice still has the inner hull and contains the germ, wholly or in part. As could then be concluded from many different experiments, the effective antineuritic principle occurs particularly in these parts of rice—and of cereal grains generally."*

*Theodore L. Sourkes: Nobel Prize Winners in Medicine and Physiology, 1966.

Petrarch to the Pope in 1352

"I am much alarmed, gentle Father, to hear of your sickness (typhus fever), and this news sent a frosty shiver over my limbs. I know that your bedside is beleagured by doctors, and naturally this fills me with fear. As Pliny said, 'In order to make a name for themselves through some novelty, they traffic with our lives. With them, not as with other trades, it is sufficient to be called a physician to be believed to the last word, and yet a physician's lie harbors more danger than any other. They learn their art at our expense, and even our death brings them experience: the physician alone has the right to kill with impunity.'

"Oh, Most Gentle Father, look upon their band as an army of enemies. Remember the warning epitaph which that unfortunate man had inscribed on his tombstone: 'I died of too many physicians.' "*

Treating vaginitis is as easy as AVC

Trichomonads...Monilia...Bacteria

You can depend on AVC—the comprehensive therapy that acts against all three major vaginal pathogens.

Monilia emerging as a major therapeutic problem—

recent studies report increased incidence, attributed in part to the use of oral contraceptives,[1-4] broad-spectrum antibiotics[5-9] and prolonged use of corticosteroids.[7]

recent evidence establishes high rate of microbiological and clinical cure with AVC.[9-11]

Comprehensive—Effective

The published record and more than two decades of clinical experience clearly establish the therapeutic value of AVC in vaginitis/cervicitis and vaginal surgery.

Easy as AVC

Contraindications: Known sensitivity to sulfonamides.

Precautions/Adverse Reactions: The usual precautions for topical and systemic sulfonamides should be observed because of the possibility of absorption. Burning, increased local discomfort, skin rash, urticaria or other manifestations of sulfonamide toxicity are reasons to discontinue treatment.

Dosage: One applicatorful or one suppository intravaginally once or twice daily.

Supplied: Cream—Four-ounce tube with or without applicator. Suppositories—Box of 12 with applicator.

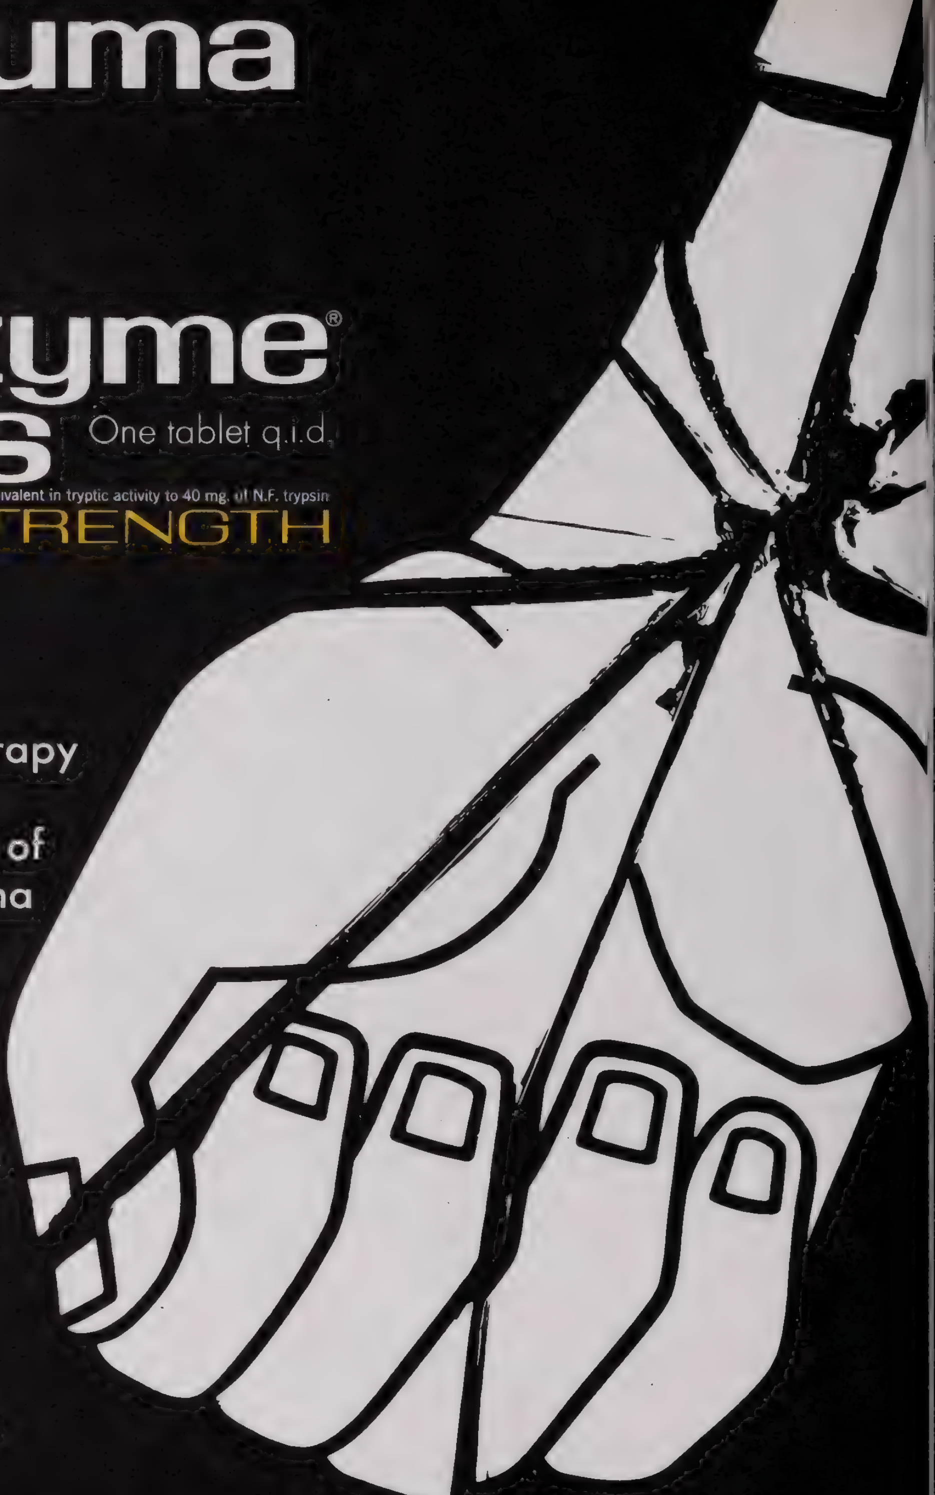
new Orenzyme® Bitabs

One tablet q.i.d.

Trypsin: 100,000 N.F. Units, Chymotrypsin: 8,000 N.F. Units.; equivalent in tryptic activity to 40 mg. of N.F. trypsin

DOUBLE STRENGTH



Proteolytic enzyme therapy specifically indicated for the rapid resolution of inflammation and edema as adjunctive therapy in accidental and surgical trauma.

1 tablet q.i.d. provides recommended therapeutic dose at lower cost.

A FULL DAY'S DOSAGE

Description: ORENZYME BITABS offers the therapeutic effects of trypsin in an oral form as adjunctive therapy for the rapid resolution of inflammation and edema. ORENZYME BITABS is convenient to use, promotes patient cooperation and is ideally suited for maintenance therapy following parenteral trypsin.
Indications: When used as adjunctive therapy for the rapid resolution of inflammation and edema, good results have been obtained in:
☐ Accidental Trauma
☐ Postoperative Tissue Reactions.
Other conventional measures of treatment should be used as indicated. In infection, appropriate anti-infective therapy should be given.
Contraindications: ORENZYME BITABS should not be given to patients with a known sensitivity to trypsin or chymotrypsin.
Precautions: It should be used with caution in patients with abnormality of the blood clotting mechanism such as hemophilia, or with severe hepatic or renal disease. Safe use in pregnancy has not been established.

Adverse Reactions: Adverse reactions with ORENZYME have been reported infrequently. Reports include allergic manifestations (rash, urticaria, itching), gastrointestinal upset and increased speed of dissolution of animal-origin surgical sutures. There have been isolated reports of anaphylactic shock, albuminuria and hematuria. Increased tendency to bleed has also been reported but, in controlled studies, it has been seen with equal incidence in placebo-treated groups. (See Precautions.) It is recommended that if side effects occur medication be discontinued.
Dosage: One tablet q.i.d.

Serum Lipid Fractions and Risk of Coronary Heart Disease*

The Framingham Study

WILLIAM B. KANNEL, M.D.†
WILLIAM P. CASTELLI, M.D.‡
PATRICIA M. McNAMARA‡
Framingham, Massachusetts

An impressive array of evidence has accumulated which links the total blood cholesterol with the development of atherosclerosis and coronary heart disease. This has stimulated much research concerning the role of lipids in atherogenesis and, as a result, virtually every blood lipid fraction has been incriminated. Nevertheless, the lipid component most basic to the atherosclerotic process remains in doubt. There are, in particular, little prospective data on which to judge. Those lipid elements incriminated in atherogenesis include cholesterol, triglyceride, phospholipid and nonesterified fatty acids. In addition, the lipoproteins and proteins which transport the lipids about in the blood have also been blamed. These include the cholesterol-rich beta-lipoproteins of the Sf 0-20 class, the triglyceride-rich pre-beta-lipoprotein of the Sf 20-400 class, the alpha-liproprotein rich in phospholipids, and the albumin fraction which carries the fatty acids about. Whether one or several of these are fundamentally involved in the pathogenetic process of atherosclerosis is not clear.

The Study Procedure

At Framingham 5,127 men and women have been followed over 14 years in a prospective study of the risk of developing manifest coronary heart disease. These individuals were classified on the basis of their cholesterol and phospholipid levels and on their serum beta and pre-beta-lipoprotein concentration early in the course of the study. Laboratory methods employed, diagnostic criteria, sampling procedures, response rates, and completeness of follow-up have been reported elsewhere.[1-10] Beta-lipoprotein fractions were measured at the Donner Laboratories under the supervision of Dr. John Gofman.

Results

The Lipid Characteristics

On follow-up of this population sample classified according to lipid characteristics, it became apparent that the risk of every manifestation of coronary disease was distinctly and impressively related to the level of each lipid and liproprotein vehicle studied. Thus, risk was related to the concentration of cholesterol, Sf 0-20 beta-lipoprotein, Sf 20-400 prebeta-lipoprotein (and to the level of phospholipid). Comparing the first with the fourth quartile, each lipid presents a gradient of risk which does not immediately suggest one particular lipid as most basic to the problem of atherosclerosis.

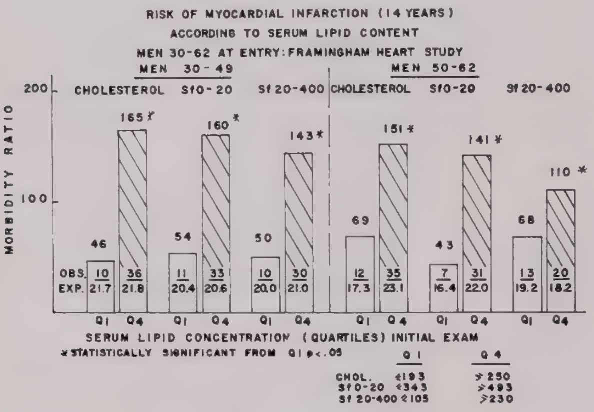

Figure 1

Figure 1 shows, furthermore, that each lipid was a better predictor of disease when measured prior to age 50 than when measured later in life. As illustrated for the beta-lipoprotein fractions in Figure 2, within the range of lipids encountered in this population, neither a safe nor a critical level of any of these lipids could be identified. Rather, the risk was proportional to the level of the lipid from the lowest to the highest values recorded in the population. The lipid levels in this population, however, are uniformly high. The antecedent lipid level was found to predict disease long in advance of its occurrence as well as in the short term.

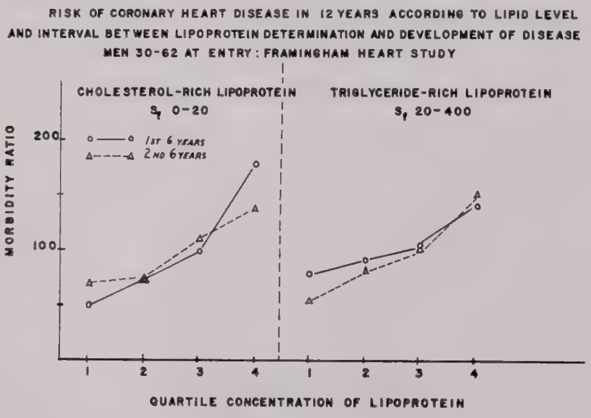

Figure 2

The Lipoprotein

No prospective data are available at Framingham for whole serum triglyceride. However, fasting whole triglyceride levels in cases compared with matched controls were examined, revealing that they are indeed higher in persons with established coronary disease, in agreement with the findings of others.[11,12] Prospective data for the Sf 20-400 pre-beta-lipoprotein, reflecting endogenous triglyceride, revealed that this lipoprotein fraction is related to risk of coronary disease in both younger and

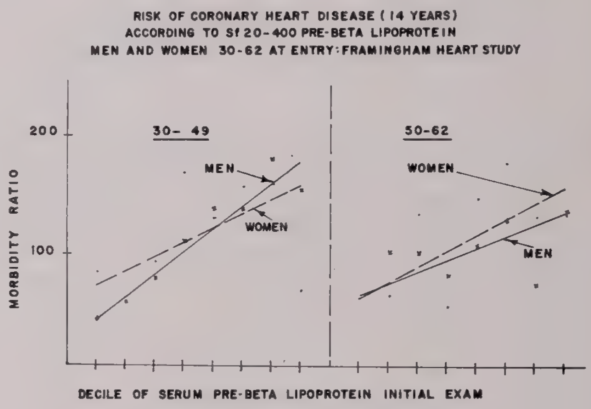

Figure 3-a

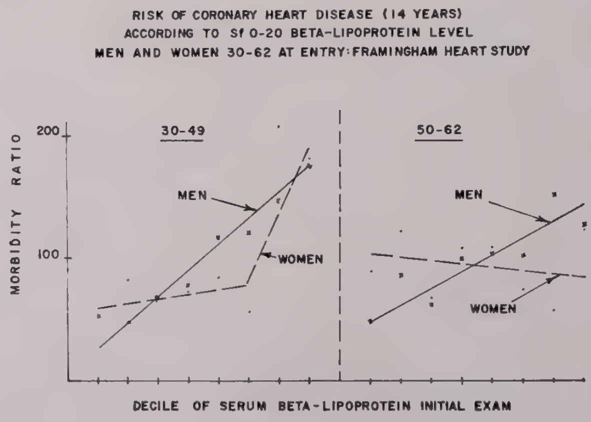

Figure 3-b

older women. The beta-lipoprotein of the Sf 0-20 class, on the other hand, is related to disease outcome in women below 50, but not above this age. In men, both of these fractions are related to risk of disease at all ages, and again it is stronger before 50 than after (Figures 1 and 3-a, and b).

Cholesterol and Endogenous Triglyceride

An examination of the risk of disease according to the level of both cholesterol and endogenous triglyceride in the serum, (as reflected by the Sf 20-400 lipoprotein fraction) reveals that each contributes to the risk. It seems clear that the risk associated with one rises in proportion to the level of the other. Whether the cholesterol was high or low, the risk rose with the level of the triglyceride. The converse was equally true. Those with both values high seemed to be worse off than those with either high alone (Figure 4). This would suggest an independent effect of each. Furthermore, as indicated in Figure 5 the risk rises, particularly in young men, in proportion to the number of lipid "abnormalities" if the value at the upper quartile of the distribution of each lipid is chosen as "high." This would also suggest that each lipid contributes to risk of disease. However, it is difficult to say whether this is actually so. As the Table shows, these lipids are highly correlated so that the level of any particular lipid also rises with the number of lipid abnormalities present. Con-

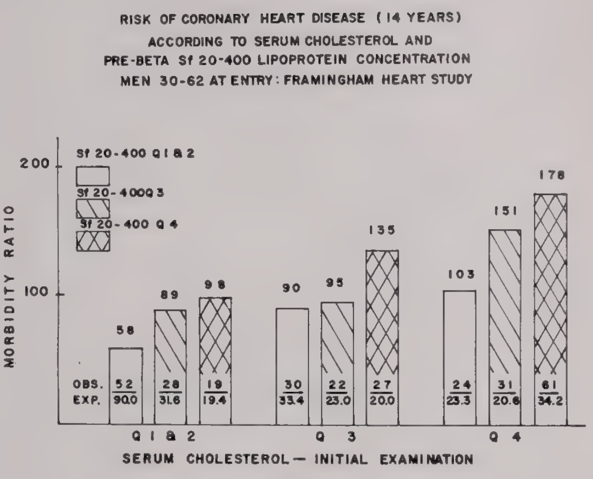

Figure 4

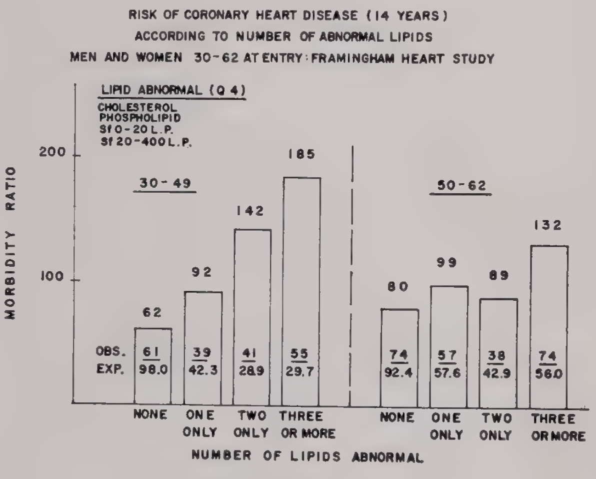

Figure 5

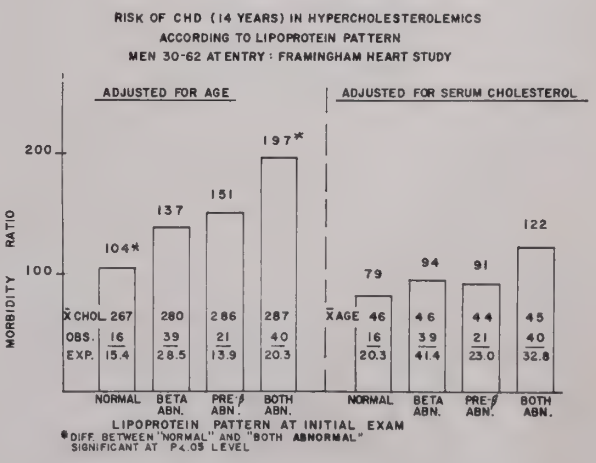

Figure 6

sequently, it is difficult to assess the net effect of each lipid fraction as a contributor to risk. Discriminate function analysis will be employed in an attempt to determine the net and joint effect of these lipids.

The Sf 20-400 pre-beta-lipoprotein level reflects endogenous triglyceride which becomes elevated in endogenous or carbohydrate-inducible hyperlipemia and in persons with diabetes.[13-15] This fraction also carries some cholesterol and, as a consequence, marked elevations may raise the total serum cholesterol concentration. An elevated cholesterol occurring in association with a high 20-400 pre-beta-lipoprotein concentration may, as a result, reflect a metabolic alteration different from that which occurs in association with beta-lipoprotein elevation of the Sf 0-20 class.

Figure 6 shows a further classification of persons with elevated cholesterol levels according to their associated lipoprotein pattern, whether predominantly beta or pre-beta or both. This suggests some differences in risk depending on the associated lipoprotein pattern. Those with both lipoproteins elevated appeared to have the highest risk, but they also had the highest average cholesterol. Whatever the pattern, it is clear that hypercholesterolemia is not innocuous. The risk generally tends to be proportional to the cholesterol level irrespective of the associated lipoprotein pattern. However, adjustment for cholesterol variations between the groups does not entirely eliminate the differences, although they are no longer statistically significant. Since adjustment for the differences in cholesterol content failed to obliterate the effect of the associated liproprotein pattern completely, it cannot be concluded on this evidence alone that risk is entirely or uniquely related to the level of cholesterol.

Obesity-Diabetes-Gout

Lipoprotein abnormality is associated with the occurrence of obesity; persons who gained weight tended to have their cholesterol level rise, particularly if they were not already obese. To an even greater extent their Sf 20-400 or pre-beta-lipoprotein level likewise tended to rise with weight gain. Diabetics also tended to have abnormal lipids, as did persons who developed gout. These conditions have been noted to be associated with an increased risk of coronary heart disease. The two major lipoprotein fractions, the beta cholesterol-rich and the pre-beta triglyceride-rich fractions, seem to contribute to risk even in persons who are not overtly diabetic, obese or gouty (Figure 7). This strongly suggests that the lipid is the culprit and not the associated metabolic abnormalities, although it is difficult to completely exclude latent metabolic alterations.

Once an attack occurred, the case fatality rate also appeared higher in those with preexisting elevated cholesterol levels. Evidently elevated cholesterol levels predisposed not only to the occurrence of attacks, but to failure to survive an attack once it occurred.

Hypertension

In animal experiments lipid-induced atherosclerosis is accelerated when hypertension is

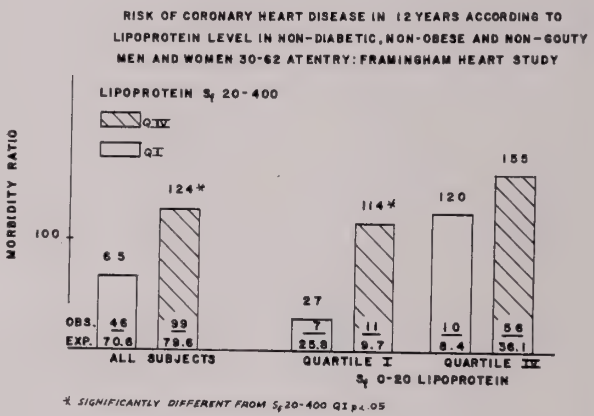

Figure 7

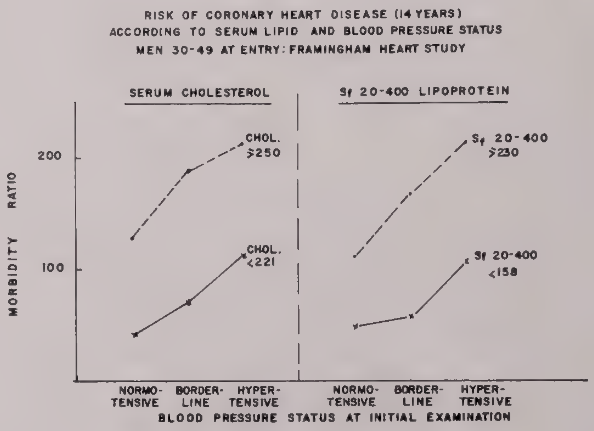

Figure 8

also induced.[16-21] Epidemiologic data appear entirely consistent with this experimental evidence. Elevated lipid or lipoprotein is more atherogenic, as evidenced by the development of clinical coronary heart disease, when accompanied by hypertension. A further increment in risk is noted in "hyperlipemic" persons as the blood pressure goes from normotensive to hypertensive levels. A high lipid level is much less ominous in normotensive individuals, being associated with a risk only modestly above the standard risk. Conversely, at any level of lipid the risk is proportional to the blood pressure level (Figure 8).

Comments

The total cholesterol appears to predict coronary heart disease as well as any other lipid or lipoprotein, but knowledge of the lipoprotein pattern may be important for other reasons. Hypercholesterolemia may be sensitive to dietary saturated fats or cholesterol. This type is apt to be associated with elevated beta-lipoprotein; but it may also be carbohydrate-sensitive and associated with pre-beta-lipoprotein.[13-15] Hypercholesterolemia may likewise be associated with high levels of both lipoproteins. If the fourth quartile concentrations used in this analysis have validity in a metabolic sense, then about half of hypercholesterolemics are at least partially carbohydrate-inducible or carbohydrate-sensitive. This may explain why the standard saturated-fat and cholesterol-restricted therapeutic diet is only moderately successful in reducing the serum cholesterol level.

Isolated cholesterol abnormality of the carbohydrate-inducible type is relatively uncommon, and the saturated fat and cholesterol-sensitive type associated with beta-lipoprotein is still the most common variety. High serum cholesterol concentrations can also occur in the absence of any dietary indiscretion, and these will sometimes not respond to any type of dietary manipulation. This is particularly true of the familial hypercholesterolemia in which there is a beta-lipoprotein abnormality without any trace of an abnormality in the pre-beta-lipoprotein.

Measures designed to alter the cholesterol:phospholipid ratio would appear futile. When hypercholesterolemic individuals are examined according to their cholesterol:phospholipid ratio there is no suggestion that high phospholipid levels actually protect persons with high cholesterol values (Figure 9). The effect of phospholipid, if any, would appear additive.

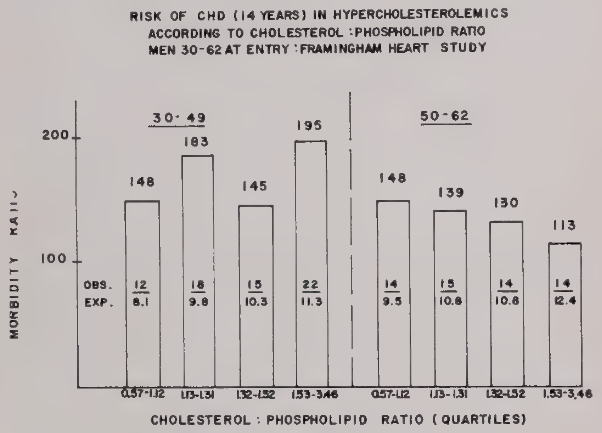

Figure 9

By usually accepted standards hypercholesterolemia does not appear to be an essential feature of atherosclerotic disease in Western civilization. Almost everyone appears to have high enough serum lipid concentrations to produce atherosclerosis. With the generally high lipid levels seen in Framingham, the risk is simply proportional to the level of a variety of lipids. Coronary heart disease is best characterized as a multifactorial disease involving an interplay of a variety of noxious factors. The more of these present, the more ominous is the contribution of the lipid to the disease outcome. When these factors are not present, lipid makes a much more modest contribution to risk.

Some persons question whether the association of lipid with atherosclerotic disease is more than a coincidence or perhaps an indicator of a more basic problem. There is also controversy as to whether hyperlipidemia is primarily an inborn metabolic error or an acquired trait. By any criterion, however, the evidence linking lipids to atherosclerosis is substantial. One most important piece of evidence, however, is still lacking. It has not been conclusively demonstrated in man whether correction of a particular lipid abnormality will result in a better prognosis or a resolution of atherosclerotic lesions; but evidence is beginning to accumulate.[22-24] Until this last link in the chain of evidence is provided, uncertainty regarding the role of lipids in atherosclerosis will continue.

Conclusions

While it appears likely that the blood lipid content, augmented by elevated blood pressure, is related to the rate of general deposition of atheromatous material, it seems clear that local factors exert a marked influence on the site of arterial deposition. These factors include the dynamics of flow, the caliber of the vessels, the metabolism of the vessel wall, and factors which promote thrombus formation and fibrin deposition. Whether the problem is primarily a genetic one involving inherited inability to cope with dietary saturated fat, cholesterol or carbohydrate, or is the result of prolonged overloading of a normal metabolic mechanism is still unknown. The answer to this question is fundamental to an understanding of the pathogenesis of atherosclerosis. At the present time the lipoprotein pattern in hypercholesterolemia would appear more important in determining the reason for cholesterol elevation and in selecting the best therapy than for estimating risk. No clear separation of potential cases from their disease-resistant cohorts appears to be achieved by further classifying hypercholesterolemic individuals according to their lipoprotein pattern.

Plasma Cholesterol Lowering Diet*

The Effect in Male Survivors of Myocardial Infarction

PAUL LEREN, M.D.†
Oslo, Norway

THE PURPOSE OF THE present study was to evaluate what effect a reduction of the plasma cholesterol concentration by means of diet would have on morbidity and mortality from coronary heart disease (coronary heart disease relapses) in male survivors of myocardial infarction.

A pilot study which preceded the present trial demonstrated that a sizeable plasma cholesterol reduction could be achieved by the planned experimental diet, and valuable experiences were gained.

The present material consisted of 412 males aged 30-64, and discharged from medical departments in Oslo during the years 1956-58, with a first diagnosis of myocardial infarction. They were allocated at random to the experimental diet group and to the control group, one to two years after their infarction.

At the start of the trial it was decided that the trial should last for exactly five years.

The comparability of the groups was thoroughly studied, and it was found that they were strictly comparable except for blood pressure. However, blood pressure was slightly higher in the diet group.

Only one coronary heart disease relapse was counted in each patient, the order of priority being: myocardial reinfarction, new cases of angina pectoris, and sudden death. Criteria for the diagnosis of reinfarction were established, and the decision was left to a diagnostic board which did not know to which group the patient belonged.

A close follow-up study was undertaken, including clinical examination with diet and weight control, serum cholesterol determination and electrocardiography, and a review of hospital records.

The Diet

The cholesterol-lowering diet was low in animal fats and in dietary cholesterol, and rich in vegetable oil.

---

*Presented at the Minnesota Symposium on Prevention in Cardiology, May 2-3, 1968 in Rochester, Minnesota.

†Assistant Professor, Oslo Kommune, Ulleval Hospital, Department VIII, Oslo, Norway.

The complete report is available in a booklet, published by Universitetsforlaget, Oslo, 1966. It was also published as Acta Medica Scandinavica Supplement 466, 1966.

In an analysis of the experimental diet as consumed by 17 selected dieters, the mean daily intake was 92 g protein, 104 g fat, 269 g carbohydrates, and 264 mg cholesterol. Daily intake of calories was 2,387.

Fat calories covered 39 per cent of total calories. The sources of fat were soy bean oil (72 per cent), fish fat (11.6 per cent), animal fat (8.8 per cent), cereal fat (5.0 per cent), and fat from other sources (2.6 per cent). Of the mean dietary fat, 21.6 per cent was saturated, 25.7 monounsaturated, and 52.7 polyunsaturated.

Results

The mean reduction of serum cholesterol in these 17 dieters was 31 per cent.

Essential details of instruction and training were given. The adherence to the diet was controlled by close personal contact assisted by a full-time, experienced dietitian working in the homes of the patients. The degree of adherence could be quantified by means of a detailed questionnaire used six times during the observation period.

Of the dieters, 62.2 per cent were judged to be "excellent" adherents, 22.1 per cent "good," 10.3 per cent "fair," and 3.9 per cent "bad."

Judging by personal contact with the controls and by a questionnaire at the end of the trial, and also by the serum cholesterol level, which remained nearly unchanged from the beginning to the end, it can be assumed that the type of food in the control group remained largely unchanged.

At the start of the trial the mean serum cholesterol value was exactly the same in the two groups (296 mg per 100 ml). From the first control examination, three months later and throughout, a significant difference in the serum cholesterol level persisted (Figure 1). The mean cholesterol reduction in the diet group was 17.6 per cent against 3.7 per cent in the control group. Of the dieters, 123 obtained a serum cholesterol reduction of $\geqq 15$ per cent, against 27 of the controls.

Myocardial Reinfarction

In the diet group 43 myocardial reinfarctions occurred in 34 patients, 10 of them fatal. In the control group, 64 myocardial reinfarctions occurred in 54 patients, 23 of them fatal.

The difference between the groups is statistically significant (reinfarction patients: $x^2 = 5.22$, $p = .022$, fatal reinfarctions: $x^2 = 4.74$, $p = .029$). But the difference did not become statistically significant until the third year of the trial.

Angina Pectoris

Of 75 dieters and 79 controls who did not have angina pectoris at the start of the trial, 10 dieters and 29 controls acquired angina during the observation period. Of these, two of the dieters and nine of the controls also had reinfarctions and have been counted as such. After excluding these patients, the difference between the groups is still statistically significant ($x^2 = 4.61$, $p = .031$).

Sudden Death

The incidence of sudden death was the same in the two groups, 27 in each. This result was not surprising. Sudden death is considered in most instances to be caused by ischemia, provoking electrical instability followed by ventricular fibrillation or heart stand-still. It is reasonable, therefore, that sudden death in survivors of a myocardial infarction, presumably with rather advanced atherosclerosis, is less related to the degree of atherosclerosis than to other factors, such as the localization of the lesions to more vulnerable areas.

Total CHD Relapses

The total number of coronary heart disease relapses was 80 in the diet group and 120 in the control group. These relapses occurred in 64 dieters and in 90 controls. The difference is statistically significant ($x^2 = 6.48$, $p = .011$), and the difference became significant during the second year of the trial.

As the diagnosis of angina pectoris can be difficult and possibly influenced by personal

TABLE

	Diet	Control
No. of men at entry	206	206
Fatal relapse (fatal reinfarct + sudden death)	37	50
Non-fatal reinfarct	24	31
Major CHD relapse	61 (P = .05)	81
All cardiovascular deaths	38 (P = .09)	52

bias, only major coronary heart disease relapses are counted in the Table. The total cardiovascular mortality as calculated by "life-table" methods is presented in Figure 2.

Age Factor

Subdividing the material into age groups, those below 60 years and those of 60 years and older, revealed that the difference in the coronary heart disease relapse rate was statistically significant only in the patients below the age of 60. So too was the relapse combination, myocardial infarction and acquired angina pectoris. The incidence of sudden death was the same in the two groups, independent of age.

In the diet group as well as in the control group, the serum cholesterol level was higher in the patients with coronary heart disease relapses than in those without. Subdivision of the material revealed that this difference in the serum cholesterol level was also limited to those under 60 years of age who had myocardial reinfarctions and acquired angina pectoris. At the age of 60 and above, there was no difference in the serum cholesterol level between those with and without coronary heart disease relapses.

No association was found between the serum cholesterol level and the incidence of sudden death in either of the two age groups.

The coronary heart disease relapses were also related to other possible coronary risk factors.

Risk Factors

Body weight had no definite influence on the serum cholesterol level or on the coronary heart disease relapse rate, except that the

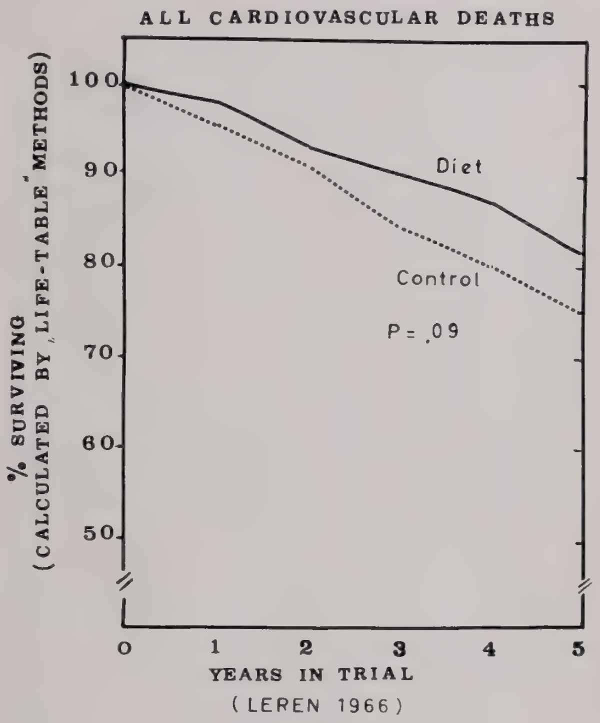

Figure 2

	N (at start)	Start value (mg/100 ml)	Mean reduction (mg)	Mean reduction (per cent)
Control:	206	296	11	3.7
Diet:	206	296	52	17.6

Fig. 1—Serum cholesterol levels in the diet and the control group during the observation time.

cholesterol level tended to be reduced in those underweight.

Blood pressure had no definite influence on the coronary heart disease relapse rate in the diet group. In the control group there was a strong trend, though statistically not significant, toward a higher coronary heart disease relapse rate in the hypertensives. This was especially true when serum cholesterol at the start was ≧ 275 mg per 100 ml. The difference in coronary heart disease relapses between these normotensive and hypertensive controls very narrowly escapes the five per cent level of significance ($x^2 = 3.22$, $p = .073$).

Smoking habits did not influence the serum cholesterol level or the coronary heart disease relapse rate in the control group. In the smoking dieters there was a suggestion, although statistically nonsignificant, toward a higher coronary heart disease relapse rate ($x^2 = 2.78$, $p = .096$).

The presence of angina pectoris at the start of the trial increased the coronary heart disease relapse rate in both groups, especially the incidence of sudden death, which in both groups together was significantly higher in those with angina than in those without ($x^2 = 7.30$, $p = .007$).

The effect of cholesterol reduction was most pronounced in those without angina pectoris at the start of the trial. The difference in the coronary heart disease relapse rate between these dieters and controls was highly signifi-

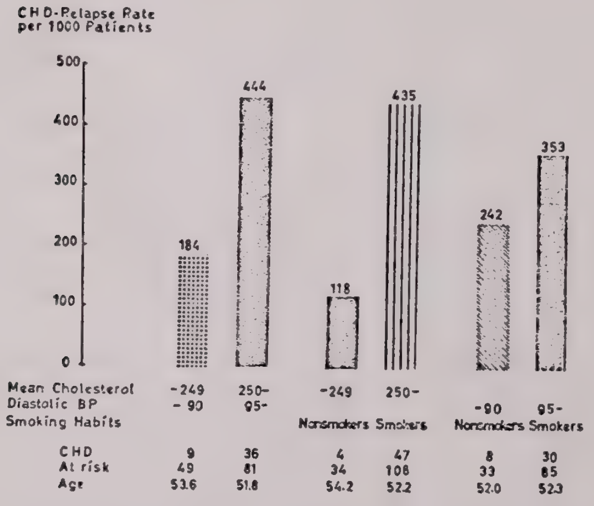

Fig. 3—Both groups. Age < 60. Coronary heart disease relapse rate in relation to combined risk factors.

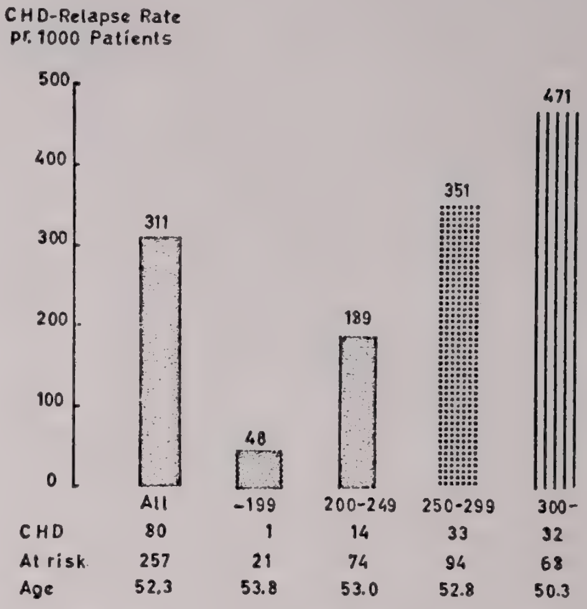

Fig. 4—Both groups together. Age < 60. Incidence of coronary heart disease to mean serum cholesterol level during the observation time.

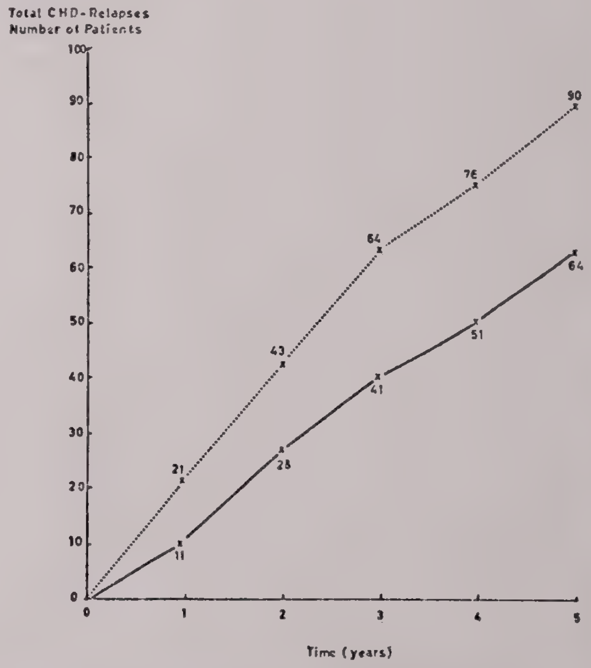

Fig. 5—Cumulated incidence of total coronary heart disease relapses.

cant ($x^2 = 10.00$, $p = .002$). In those with angina pectoris at the start of the trial the difference in the coronary heart disease relapse rate between dieters and controls was not statistically significant.

A significantly reduced relapse rate in the dieters as compared with the controls was found only in those with a normal relative heart volume at the time of the primary infarction.

The presence of a pathological electrocardiogram at the start increased the coronary heart disease relapse rate in both groups, especially the incidence of sudden death, which in both groups together was significantly higher when the electrocardiogram was pathological ($x^2 = 11.80$, $p = .001$). However, the reduction of the coronary heart disease relapse rate in the dieters was the same, whether the electrocardiogram at the start was normal or not.

Serum Cholesterol

Investigation of the relation of coronary heart disease relapse rate to the coronary risk factors which can be influenced by preventive measures, viz., serum cholesterol, blood pressure, and tobacco smoking, revealed that the serum cholesterol level was the factor which had by far the strongest influence on the coronary heart disease relapse rate.

When the groups were analyzed together for this purpose, it appeared that in the normotensives with a low serum cholesterol level and in the non-smokers with a low cholesterol level, the coronary heart disease relapse rate was significantly reduced as compared to the hypertensives with a high cholesterol level and to the smokers with a high cholesterol level (Figure 3). The respective tests of significance are: $x^2 = 8.05$, $p = .005$, and $x^2 = 9.99$, $p = .002$.

The correlation between the serum cholesterol level and the coronary heart disease relapse rate at age below 60 (both groups together) was striking (Figure 4). The data are as follows: a mean serum cholesterol value during the trial < 200, 200-249, 250-299, and $\geqq 300$ (mg per 100 ml) was associated with a total coronary heart disease relapse rate per 1,000 patients of 48, 189, 351, and 471 respectively.

In the patients who had overcome their previous myocardial infarction with no obvious signs and symptoms of heart disease, that is, without angina pectoris and with a normal heart volume and a normal blood pressure, a highly significant difference between the diet group and the control group in the total coronary heart disease relapse rate was found ($x^2 = 10.15$, $p = .001$).

Thus, in these subjects, who are believed to constitute the subgroups of the material most comparable with the general male population at the same age level, dietary reduction of plasma cholesterol proved to be most effective in the prevention of coronary heart disease relapses.

Conclusion

The effect of a plasma cholesterol lowering diet on the coronary heart disease relapse rate was studied for five years in a group of 206 male infarction patients and the results compared with those in another group of 206 patients who continued on a conventional diet.

The patients were allocated to the groups after a strictly randomized system, and the groups matched well.

The cholesterol lowering diet reduced the incidence of total coronary heart disease relapses.

There was a distinct difference in the effect on patients below the age of 60 and those of 60 and above. The difference was highly significant in the younger age group, but not in the older.

Sudden death occurred with an identical rate in the diet group and the control group, so that the significance applies to myocardial reinfarction — fatal and non-fatal — and to new cases of angina pectoris, but not to sudden death.

The most striking effect of dietary reduction of the plasma cholesterol was encountered in those who had recovered from their previous myocardial infarction with no obvious signs and symptoms of their heart disease. These subjects are thought to be most comparable to the general population.

Classified advertising rates are twenty (20) cents a word; minimum monthly charge $5.00; key number, fifty (50) cents additional.

Replies to advertisements with key numbers should be mailed in care of Minnesota Medicine, 375 Jackson, St. Paul, Minn. 55101.

TEN MAN MULTISPECIALTY group needs an orthopedist, ophthalmologist and another pediatrician. New clinic building, complete laboratory and x-ray facilities. 180 bed modern hospital across street from clinic. Early share-holder status. Salary open. Write or call the Lenont-Peterson Clinic, Ltd., C. A. Tietz, M.D., area code 218, 741-4292, Virginia, Minnesota 55792.

WANTED: Young physician for association leading to partnership with four well established General Practitioners in fast growing suburb of St. Paul. Excellent clinic facilities in nearly new, partnership owned, well equipped, medical center building. Write: MINNESOTA MEDICINE-421, 375 Jackson, St. Paul 55101.

PSYCHIATRIC RESIDENCIES: We offer nothing but excellent psychiatric training in a stimulating, well organized program located in a culturally advantaged community. Approved psychiatric training. Traverse City State Hospital, Michigan Department of Mental Health. Three and five year programs. Salary, 3 year program: $10,669; $11,191; $12,131. 5 year program: $12,152; $14,031; $16,328. $21,944; $23,093. NIMH-GP stipends available. Located in Michigan's serene, scenic recreation area on Grand Traverse Bay. Contact Dr. Paul E. Kauffman, Director of Training, Traverse City State Hospital, Traverse City, Michigan 49684. An equal opportunity employer.

YOUNG EXPERIENCED GP with family and excellent background desires to relocate. Will consider any location if financially attractive. Write: MINNESOTA MEDICINE—437, 375 Jackson, St. Paul, Minnesota 55101.

640 ACRES, 360 tillable, fertile sandy loam soil, buyer receives ⅓ of 1969 crop. $20,000.00. Johnson Realty, Hallock, Minnesota, Phone: 843-2103.

GP AND OB GYN wanted to join two GPs, surgeon, and internist in suburban group. Excellent nearby hospital. Salary first year, then partnership. Write MINNESOTA MEDICINE-436, 375 Jackson, St. Paul 55101.

THREE PHYSICIANS WANTED: Emergency room at St. Paul, Minnesota, June 1, 1969. 450 beds, expansion 600 beds, 1970. Minimum guarantee $25,000 per year. Work week 28 hours. Contact Thomas W. Votel, M.D. 612-488-6777.

GENERAL PRACTITIONER wanted to join well-established practitioner. New clinic building—90 miles east of St. Paul—city of 14,000. Early partnership with full hospital facilities. Ideal location. L. W. Picotte, M.D., Chippewa Falls, Wisconsin.

WANTED: General Practitioner or Internist, to join four man group in St. Paul. Partnership possible in one year. Dr. V. L. Sommerdorf, 1239 Payne Avenue, St. Paul, Minnesota 55101.

INTERNIST, PEDIATRICIAN, ORTHOPEDIST, GENERAL PRACTITIONER to join nineteen-man Wisconsin group located in college community of 40,000 with excellent hospital facilities. For further information contact D. R. Griffith, M.D., Midelfort Clinic, Eau Claire, Wisconsin.

WANTED: General practitioner to join two young general practitioners in well-established practice in suburban St. Paul. Excellent office space with lab, x-ray, and emergency room. Salary negotiable, with an association leading to early partnership opportunity. Write MINNESOTA MEDICINE 412, 375 Jackson St., St. Paul 55101.

INTERNIST AND GENERAL PRACTITIONER wanted to join a five-man clinic group in Minneapolis. Complete laboratory and X-ray with board roentgenologist. Excellent hospital staff associations. Salary arrangement to start with, early partnership. Write MINNESOTA MEDICINE—289; 375 Jackson, St. Paul, 55101.

OPPORTUNITY FOR CAREER in occupational medicine with large corporation. Multiple locations. Salary plus fringes. Immediate openings in three locations. Give resume. Write: MINNESOTA MEDICINE—432, 375 Jackson, St. Paul 55101.

THREE MAN group in North West Wisconsin Resort, State Conservation and Retirement Area needs two more physicians adequately to serve their practice. Facilities offered are three-room physician suites, X-ray and lab under AMT technician, RN-only nursing personnel. New accredited thirty-two bed hospital and forty-six bed nursing home. Deer and duck hunting, fishing within five minutes of town. Internist most needed; generalists welcomed. Will meet any reasonable salary request. Partnership after one year. Write: MINNESOTA MEDICINE—365; 375 Jackson St., St. Paul 55101.

Diet High in Unsaturated Fat[*]

A Controlled Clinical Trial

SEYMOUR DAYTON, M.D.[†]
MORTON LEE PEARCE, M.D.[‡]
Los Angeles, California.

It was known 10 years ago that certain dietary changes were capable of lowering the serum cholesterol concentration, and there was reason to suspect that such changes might retard the development of atherosclerosis and its complications. However, this inference was by no means a foregone conclusion, particularly as it applied to persons during and beyond middle age. The need for a clinical trial was apparent.

Domiciliary[§] Study

Use of the Domiciliary Unit in the Los Angeles Veterans Administration Center for such a trial readily suggested itself. This unit houses about 2,600 veterans, disabled or elderly, but ambulatory, with mean length of stay almost two years, about as long as in any large institution housing adults. In 1959 we began a controlled clinical trial of a diet low in saturated fat and supplemented with unsaturated fat, the trial ending in January, 1968. We are able to present data on morbidity and mortality which are complete and final, although not yet analyzed in full detail.

Age

The subjects were volunteers from the domiciliary population, aged 54 and above, with mean age 65.5 years. After baseline evaluation subjects were assigned at random either to a control diet or to the experimental diet. Ultimately started on the diets were 846 men, half in each group. Meals were served ad libitum, cafeteria style, from service lines which were separated physically. Service was controlled by color-coded meal tickets punched at each meal to provide individual attendance

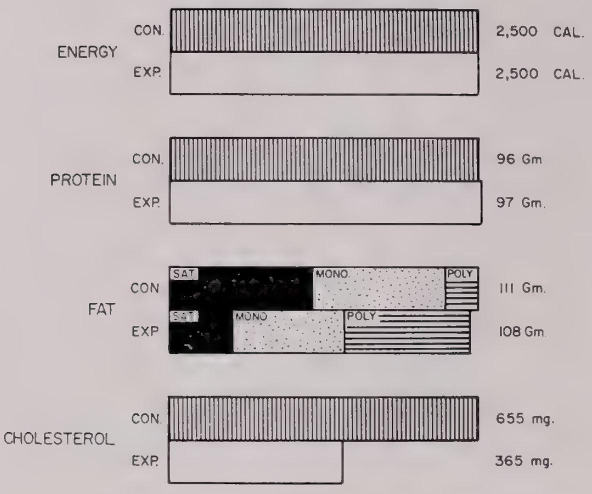

Fig. 1—Major nutrients of control and experimental diets; mean values shown are mean daily intakes for the individual receiving a typical tray at each meal.

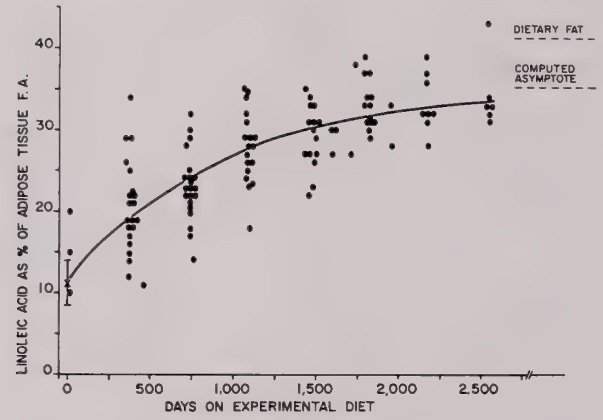

Fig. 2—Linoleic acid content of subcutaneous tissue in participants on the experimental diet. Subjects were selected for good adherence, defined as 80% or more of possible meals taken in the dining room. Values at day 0 are mean ± S.D. of 120 individual values.

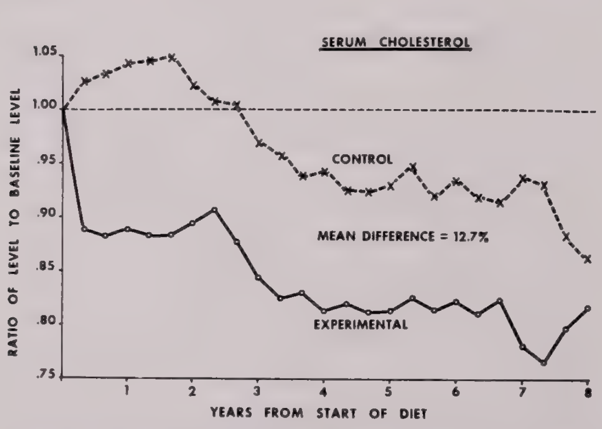

Fig. 3—Changes in serum cholesterol level of control and experimental groups. Each point is the mean of all values for the given interval.

records. The study was carried out on a double-blind basis.

The Controls

The control subjects received a conventional American diet of typical composition. The experimental diet was designed to simulate a conventional diet as closely as possible, in order to foster prolonged cooperation of even minimally motivated participants, while at the same time embodying maximum change in the character of dietary fat compatible with the objective of acceptability.

The Two Diets

Figure 1 summarizes the composition of the two diets as determined by analysis of weekly collections. They were comparable with respect to caloric content, protein, and the quantity of fat; however, the fat of the experimental diet was substantially more unsaturated, containing almost four times as much linoleic acid as the control diet and correspondingly less saturated fatty acid. The cholesterol content of the experimental diet was also reduced by nearly half in comparison with the control diet.

It was hoped and expected that no change in body weight would occur. Mean weight in both groups did in fact remain within 2% of the starting levels, although some individuals showed wide variations in both directions.

Adherence to diets in this institution is not enforceable and was imperfect, but it could be monitored. Mean adherence, as estimated by individual dining-room attendance, was approximately 80% for subjects of both groups during periods in which they were actually residing in the Center and participating in the study.

Figure 2 shows evidence confirming the fact that adherence estimates based on dining-room attendance are realistic. This is a plot of the rise in linoleic acid of subcutaneous fat in the experimental group, limited to subjects selected for good dining-room attendance, whose average attendance was 92% of the theoretical maximum. Although the rise was slow, the level approached the linoleic acid content of the experimental dietary fat, indicating that this was in fact the dominant fat source in these individuals.

The Results

Serum Cholesterol

Figure 3 demonstrates total serum cholesterol data over the eight-year period. The mean starting level was 233 mg/dl in both groups. The reason for the gradual decline in serum cholesterol in the control group is not known to us. We take the difference between the two groups as reflecting the net effect of the experimental diet. It amounted to 12.7%.

Table 1 bears a summary of data concerning comparability of the two groups in regard to factors which might have influenced the outcome of the study. We did not attempt to evaluate ethanol intake or exercise, assuming that meaningful quantitation of these would be out of the question. With regard to those factors shown, randomization of the subjects was expected to render the two groups comparable, and it did so. Please note the indication, in the right-hand column, that the participants were not all free of overt atherosclerotic disease. In these characteristics, as in regard to the others, the two groups were comparable. The only identified difference was in a characteristic—severe baldness—which is not known to be related to atherosclerosis and which was included in our data collection as a whim.

Discharge and Withdrawals

Table 2 shows information concerning discharge from the institution and re-entry; there was a good deal of coming and going. As both groups were comparable in this regard, this undesirable mobility was not a source of bias in the clinical data.

There were (Table 3) differences in the rates of withdrawal from the study. Of the 422 control subjects, 58 (14%) withdrew, the commonest reason being an order for a therapeutic diet. The withdrawal rate in the experimental group was higher, but only in the first two years. The dominant reason for the higher withdrawal rate was dissatisfaction with filled milk, the product available to us

TABLE 1

Comparability of the Two Groups of Participants

Two groups comparable at start in regard to:	
Race	Serum cholesterol
Religion	Serum total lipid
Age	Smoking habits*
Height	Cardiac compensation
Weight	Previous angina pectoris

in the early part of the study being of variable quality. Because of the differential in drop-out rates, any stratification of outcome data based on this characteristic would involve some risk of bias.

Double-Blind Study

The trial was double-blind. As a check on the integrity of this feature insofar as the medical staff was concerned, our three clinic physicians were asked, during the seventh year of the study, to guess at the diets of the subjects at 229 consecutive examinations. In the 104 instances in which an opinion was ventured, only 53 cases were correctly classified: a number compatible with random guessing. Our doctors thus displayed a gratifying degree of ignorance on this point.

Mortality

Men in the Center and in the study had electrocardiograms done, were re-examined annually, and were seen by our staff on the occasion of any hospitalization. At the end of the study, a search was conducted through the Veterans Administration Central Office for death certificates of men who were out of the Center and whose status was unknown. Completeness of mortality checks through the Veterans Administration is known to exceed 95%. Since the majority of our subjects who died did so in our Center, mortality ascertainment is estimated to be about 99% complete. We had no systematic morbidity surveillance for men once outside the Center, but some non-fatal events outside the Center came to our attention in various ways. Regardless of the place of a clinical episode or a death, it was recorded as representing an atherosclerotic event only if it met previously established criteria to the satisfaction of both of the authors. Unsupported death certificate diagnoses and unsupported diagnostic statements of physicians were not accepted. The autopsy rate for deaths within the Center was 80%, and for all deaths 65%.

Major Cardiac and Cerebral Events

The following data include every man who was ever assigned to diet regardless of his subsequent status. Furthermore, all subjects are followed to the end of the trial or to death, if earlier, regardless of non-adherence, regardless of subsequent withdrawal, and regardless of absence from the Center.

Table 4 presents data on the chief end points of the study. Myocardial infarctions, sudden deaths, and cerebral infarctions were all less numerous on the experimental diet. None of these individual differences are significant, but a combined look at disabling or fatal coronary and cerebral events, shown at the bottom of the Table, yields a difference which is significant at the 99% confidence level. If silent myocardial infarcts are included, the difference becomes smaller than shown here but is still significant at the 98% confidence level.

Definite Events

Table 5 shows complete data on "hard" end points: that is, events ascertainable with, we believe, little diagnostic error. The difference in the two groups in regard to myocardial infarction is augmented when silent myocardial infarctions are excluded. Events in peripheral vascular sites were approximately equal for the two groups.

Indefinite Events

Table 6 shows data on "soft" events, such as angina pectoris, and a variety of episodes classified as "possibles" or "probables." No differences are apparent, either for individual categories or for totals.

Mortality data are shown in Figure 4, in terms of total numbers of deaths. Deaths attributed to atherosclerotic events ultimately numbered 70 in the control group and 48 in the experimental group, with a p value less than 0.05 by chi-square. When we look at total mortality, in the upper pair of curves, we find differences for the first three or four years nearly identical to the differences due to atherosclerotic events; however, the curves for total deaths converge in the latter part of the study. Of course, all mortality curves have to converge ultimately, particularly in elderly men, but this convergence occurs earlier than we would like to see it. We shall have to take a careful look at causes of death

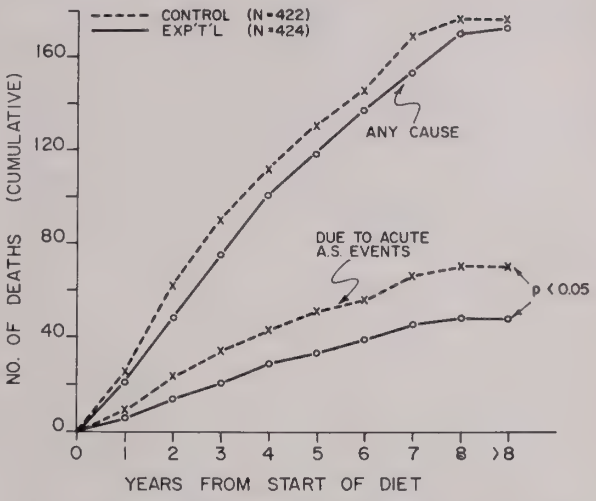

Fig. 4—Mortality data—total mortality and deaths due to acute atherosclerotic events. The latter figures include 10 control cases and 9 experimental cases in which other diseases contributed to the death. The number of cases in the trial beyond 8 years was small (56 in each group) and the duration of observation beyond 8 years was in no instance more than 4 months. Abbreviation: A.S. = atherosclerosis.

in the last three years, but have not yet had the opportunity.

Fatal Atherosclerotic Events

Types of fatal atherosclerotic events are seen in Table 7. The difference in totals is contributed to by all categories except myocardial infarction, for which numbers of fatalities were equal.

Finally, Table 8 presents data on fatal atherosclerotic events stratified by age of the subjects at entry into the study. The cut point between the two age strata occurs at age 65.5. The data are computed by the life table method. Above the age of 65.5 there is little difference between the two diet groups, most of the difference occurring among men aged 54 to 65.

Conclusions

In summary, we have completed a double-blind clinical trial of a diet low in saturated fat and high in unsaturated fat. The diets employed sustained a mean difference of 13% between serum cholesterol levels in the control group and levels in the experimental group, during periods in the Center. The subjects were men over 54 years of age, some of them with pre-existing complications of atherosclerosis. The experimental group had a significantly lower incidence of major atherosclerotic events during the study than did the control group. Furthermore, fatal atherosclerotic events were less numerous in the experimental group than in the control group. Most of this difference occurred in the younger subjects, aged 54 to 65 at the start of the study.

Red Light

A young student nurse was taking a driver's license test. Accompanied by a state policeman, she drove through a red light without noticing.

"Young lady, what does a red light mean to you?" the trooper inquired sarcastically.

Quick as a flash she answered, "A bedpan!"*

Changes of Diet and Risk Factors*

in the National Diet-Heart Study*

E. S. FETCHER, Ph.D.[†]
Minneapolis, Minnesota

LIFE-LONG LOW LEVELS of serum cholesterol are associated with low incidence rates of coronary heart disease. The question *behind* the National Diet-Heart Study[1] has been asked many times, and still is being asked: Will changing diet to lower the serum cholesterol level also lower the incidence of first clinical episodes of coronary heart disease among middle-aged men? It was estimated that tens of thousands of clinically healthy subjects would be needed in a five-year experiment. Such an experiment was too large, complex, and crucial to undertake without knowing if it could be done; therefore, the National Diet-Heart Study[1] was mounted to assess its feasibility. The study addressed itself to many problems of feasibility but only three will be considered here: (1) Will enough healthy, middle-aged men volunteer from the general public for a big diet study: that is, eligible volunteers, willing to change their habits and adhere to a prescribed dietary regimen? (2) What is the effect of the dietary prescription on levels of serum cholesterol and on other risk factors? (3) Is a parallel experiment practical on men in a mental hospital under well-controlled conditions? What are the responses of the free-living men as compared with the institutionalized men?

Design and Methods

Six research centers adopted a common protocol for studies in five metropolitan areas on volunteers from the general public; with the sixth center using mentally retarded patients at the Faribault, Minnesota, State School and Hospital. The entire study was double-blind, neither the subjects nor the staff knowing diet assignments or individual blood lipid responses. The principal end point criterion was change of serum cholesterol, and the only purposeful intervention was on the fat composition of the diet. Changes of other variables, such as body weight, blood pressure, and smoking, were observed and followed.

The Diets

Three diets were tested in all six centers: Two were designed to lower serum cholesterol; and the third, called "D," was planned as a control diet, almost like the U.S. diet. It was a failure and contributed few useful results. Compared to the usual U.S. diet, the two treatment diets, if eaten according to their design, would have cut the intake of saturated fats and of dietary cholesterol by 60 per cent, and raised polyunsaturated fat intake three or four times. One of the diets, termed "B," was designed to reduce total fat intake from a U.S. average of about 42 per cent of total calories to 30 per cent, and the other, termed "C," would reduce it to 35 per cent, both diets avoiding extreme food alterations. Although B and C were intended to be somewhat different, the serum cholesterol responses were essentially the same. Therefore the results are pooled here.

The Subjects

The subjects were clinically healthy men, 45 through 54 years old, eating average U.S. diets, purportedly willing and able to follow the dietary prescriptions. Data were collected on the subjects during screening examinations and a baseline period and were then used to classify the men into stratified, matched cohorts for random, blind assignment to experimental diets. Thus men were not allowed to choose among the three diets. Subjects and their wives were taught which foods to use and which to avoid. At first, after diet changes, the men returned frequently to the clinics to give blood samples and nutritional and clinical data; then the interval between visits was lengthened to eight weeks.

Results

Of the base populations first reached by mail, 11 per cent volunteered for the study. The volunteers were screened, and one third were excluded about two to one (23% and 10%) respectively for medical and nutritional reasons. Approximately eight per cent of the men withdrew before the start of assigned diets, leaving 60 per cent of those examined to be randomized: about 1200 men in five cities and 220 at Faribault. Of those, 12 per cent dropped, or were dropped, from the study in the course of a year; the highest loss rates being early in the year.

The mean baseline serum cholesterol concentration for men in all five cities was close to 230 mg/dl, and the means for the cities varied from 222 to 233. Faribault was low at 208 mg/dl. (Faribault dietary information available at the time was inadequate to explain that low level.)

There was a greater variation among Centers in the proportions of men, at baseline, with high serum cholesterol levels (280 to 350 mg/dl): from 20 per cent of men in one city to 7 and 8 per cent in two others, and 5 per cent at Faribault. These are important differences because baseline levels have been shown to affect serum cholesterol response to a specific diet change.[2]

Serum Cholesterol Changes

Table 1 shows the mean baseline serum cholesterol concentrations and changes for free-living subjects in all five cities together, and for Faribault. Serum cholesterol levels of free-living men on diets B and C fell from a baseline average of 230 to 204, a decrease of 26 mg/dl, or 11 per cent of baseline level. Faribault men on B and C diets went from their low mean of 208 to 172, a decrease of 36 mg/dl, or 17 per cent—considerably more than the free-living men, no doubt because their foods were almost fully controlled.

B and C diets depended heavily on special fat-modified foods made for the study; another

TABLE I

X	204†	–26	–11%	—	—	—

*612 men

†41 men—one city only

‡91 men

treatment diet, X, tested in one of the cities, did not. In the X diet the men used only foods available commercially, and their average decrease was identical to that of all free-living men on B and C, 26 mg/dl, or 11 per cent. But those men on the X diet did not do as well as their fellows in the same city on B and C. Hence special foods did help the subjects to reach lower serum cholesterol levels, though they were not essential for effective overall diet change. This is of interest in that suitable foods are becoming increasingly available to the public.

Influence of Weight

Two factors which affect serum cholesterol response to diet alteration are body weight change and baseline serum cholesterol level. With decreasing body weight serum cholesterol generally falls; with increasing weight it rises. Table 2 shows the influence of the baseline cholesterol level on response to what was probably the same average diet change. The third of the men with low initial levels, averaging 188, decreased 18 mg/dl, whereas the men in the upper third of the baseline distribution, averaging 268, had a decrease of 35 mg/dl. So, from the high third to the low, the response was half as great—35 to 18; yet the baseline serum cholesterol level was only 30 per cent less. The same pattern was observed at Faribault. Generally, there will be a much greater response to the same diet change from high-level men than from men who already are low.

Table 3 represents the calculated target serum cholesterol changes for the diets compared to those observed, for all B and C men in the five cities.[3] Faribault was close to the goal, as was expected because the men had access only to the meals served. The averaged calculated target for five cities was a decrease of 42 mg/dl, and the observed change was 26-27, or 63 per cent of target, a value that may be a good index of adherence to the prescription. There was some variation among the averages of the cities from 45 per cent of target to 83 per cent, even under the common protocol. However, that range would be less if the populations were corrected for "responsivity," due to their differing proportions of high and low-cholesterol men at the start.

Discussion

How might these very real and significant changes, and the recorded variations in blood pressure and smoking, affect the overall risk of coronary heart disease? A rough approximation, entailing some dubious assumptions, is given in Table 4. At Faribault the lowering of serum cholesterol plus an unexplained 10 mm systolic blood pressure decrease, add up to a 47 per cent predicted decrease in risk. In the five cities, measured changes of systolic blood pressure and of serum cholesterol, plus reported changes of smoking habits during the experiment, add up to a predicted 34 per cent lowered risk. The predicted risk change was −41 per cent from the calculated target lowering of serum cholesterol, with no change of blood pressure or smoking.

Looking ahead a little, on the supposition that diet, serum cholesterol, atherosclerosis, and heart disease are indeed causally related, we might well be more concerned about the coronary heart disease incidence rates in our children when they reach our age than we are about our own generation. For, with the post-World War II opulence, a great many of these

TABLE 4

Approximations of Change of CHD Risk Status for
B & C Diet Groups
Diet-Heart Study, First Year

Assumptions:

1. Decreased risk factor levels are maintained long-term by men completing study.
2. Changes of risk factor levels change risk status to Framingham risk levels.
3. Body weight changes are too small to change risk status.

	Relative Risk Status Change from Risk Factors:

612 men completing study	–28	–2	–4	–34*
Target	–41	0	0	–41

*Inclusion of drop-outs decreases sum of risk change by 4%.

young people will have been exposed to a richer diet for more years than we were, as well as to more cigarette smoke. So we may have even higher incidence rates, and at younger ages, than are now current—unless the necessary is done soon.

Success of any major public health effort in this direction, whether in the form of a mass field trial or a generalized attempt to change food habits, must depend heavily on an informed public and on full knowledge and collaboration of the medical community, and of major segments of the food industry.

Conclusions

Reverting to the National Diet-Heart Study and its assessment of feasibility of definitive experiments on the effect of diet alteration on CHD incidence, the Study Group concludes that, given a reasonable study design: (1) Enough eligible men would volunteer from the general public to yield the numbers of subjects needed for a definitive experiment. (2) Drop out rates and adherence to dietary prescriptions would be tolerable. (3) The probability of lowering incidence of coronary heart disease significantly—perhaps by 30 per cent—in free-living male volunteers is high enough to warrant a mass field test of the prevention hypothesis. That probability is higher for men at relatively high risk, since their potential for improvement is greater than for men at lower risk. (4) Institutional studies can be expected to define more exactly the changes and their results than can studies on free-living subjects, but would probably leave unanswered the question of what alterations might be achieved by the general population.

Recommendations

Key recommendations of the Final Report on the study are that: (1) Definitive experiments on coronary heart disease and diet, and possibly other risk factors, should be planned and put in operation as soon as possible. (2) Subjects should be randomized between control and experimental cohorts. (3) The studies should be done on free-living subjects and possibly on institutionalized subjects; concentrating on the coronary-prone because they represent the major public health program, and because their risk status should change more for a given diet change than that of other men, thus minimizing the number of subjects required. (4) Concurrent studies on primary and secondary prevention should be considered.

When this study was started about ten years ago there already was much epidemiological and other indirect evidence to favor the hypothesis that the incidence of coronary heart disease could be decreased by a suitable change in the fat composition of the diet. It had been found that in populations experiencing a high incidence of coronary heart disease, the serum cholesterol values tended to be high along with the dietary intake of saturated fats. Furthermore, it had been demonstrated that the serum cholesterol level could be influenced by diet, particularly by the quality and quantity of fats. However, the hypothesis had not yet been tested by direct experiments in which the diet of a population was changed to satisfy the requirements of the hypothesis, and in which the development of manifestations of coronary heart disease had been observed over a sufficiently long period. We felt that the feasibility of dietary prevention of coronary heart disease could be conclusively determined only by means of such an experiment.

Coronary heart disease and its ultimate con-

sequence, coronary death, are quite common in the United States. Figure 1 shows, however, that they are still more common in Finland. This diagram shows the mortality among middle-aged men in a number of countries due to category B 26 of the International Classification of Diseases. Category B 26, although not exactly synonymous with coronary heart disease, is the closest approach to it in official vital statistics. Figure 1 shows the mortality within only one narrow age class. Figure 2 indicates that much the same relative differences prevail in other age classes as in Finland, the United States, England, Sweden, France and Japan. These facts explain why our study is being carried out in Finland.

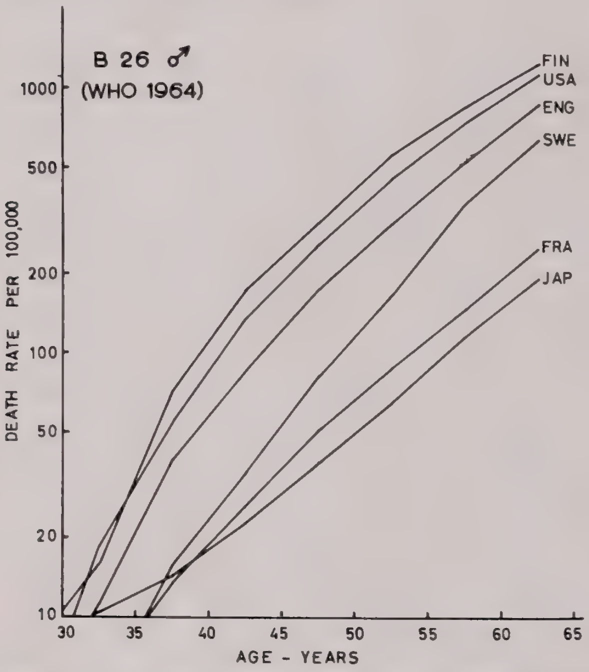

Fig. 2—Age-specific mortality (per 100,000 annually) due to arteriosclerotic and degenerative heart disease. (FIN = Finland, ENG = England, SWE = Sweden, FRA = France, JAP = Japan)

Plan of Study

Our study was started in two mental hospitals near Helsinki in 1958 (Figure 3). One of them, designated Hospital N, had the diet changed so that a large part of saturated fat was replaced by soybean oil, whereas the other hospital, Hospital K, was kept as the control without any intentional dietary change. In early 1965, when the experimental diet had been in use in Hospital N six years, the roles of the hospitals were reversed by returning Hospital N to the normal diet and by placing Hospital K on the experimental diet. It is our intention to continue the experiment according to this cross-over design for a number of years.

This report deals mainly with the observations made during the first six years of the experiment and on male patients only.

The patients ranged in age from 34 to 64 years at the beginning of the experiment. All patients within this age range who were not mentally or physically heavily incapacitated were included.

Although mental hospital populations generally do not change rapidly, a certain number of subjects were lost in both hospitals through discharges to other hospitals or home or through deaths. The average annual loss of subjects was about 15 percent. In order to keep the number of subjects in the study approximately constant, new subjects were added annually. The total number of male subjects studied during the first part of the experiment was 327 in Hospital N and 254 in Hospital K.

Diets

At the start the diets in both hospitals were similar and typical of Finnish diets. They contained large quantities of fat of the saturated type derived mainly from whole milk and butter. The total fat contents of the diets were about 33% of the food energy, and more than one half of this came from milk fat, which contributed about 17% to the total food energy.

Change from Milk Fat to Vegetable Fat

On January 1, 1959, the diet in Hospital N

1966		
1967		

Fig. 3—Design of our study.

was changed in two principal respects. First, whole milk was replaced by an emulsion of soybean oil in skim milk, and second, butter and ordinary margarine were replaced by a new brand of margarine containing considerably more unsaturated acids than commercially available brands. The effect of these changes was that the milk fat present in the original diet was almost totally replaced by vegetable oils, mainly soybean oil.

Increase in Polyunsaturated Fats

Figure 4 shows how the dietary change in Hospital N increased the quantity of polyunsaturated fatty acids about three-fold and decreased that of saturated acids by one half, and thus rendered the dietary fatty acid composition of the experimental hospital greatly different from that of the control hospital. This diagram shows the mean fatty acid compositions of the hospital diets during the whole six-year period. (S = saturated, M = monounsaturated, P = polyunsaturated). The total content of fat was slightly higher in Hospital K, but it had been so before the experiment started and we could not change it.

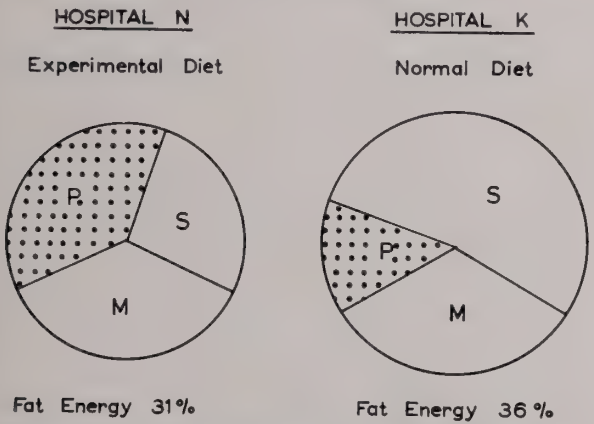

Fig. 4—Fatty acid compositions of the diets in the two hospitals (S = saturated, M = monoethenoid, P = polyethenoid)

Blood Lipids

Blood samples for lipid determinations were collected from the study groups at least once a year, and from these samples cholesterol levels were determined. Triglycerides and lipid phosphorus were determined less frequently.

Serum Cholesterol

The mean serum cholesterol levels in the two hospitals are shown in Figure 5. The initial cholesterol appeared to be somewhat higher in Hospital K; the difference, however, was not statistically significant. It could be accounted for, at least partly, by the higher content of the dietary fat and cholesterol in Hospital K. The change of the diet caused an early fall in the cholesterol value in Hospital N, but mean cholesterol values remained stable during the six years of the experiment.

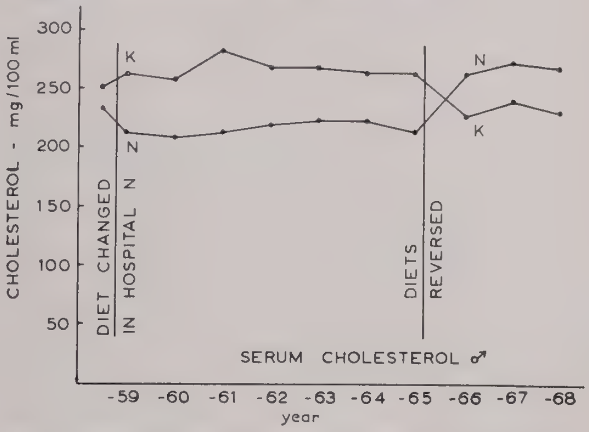

Fig. 5—Mean cholesterol levels of men in the two hospitals.

The average cholesterol level during the six years after the change of the diet was 217 mg in Hospital N and 268 mg in Hospital K: a difference of about 50 mg between the levels of the two hospitals; and this difference was statistically highly significant at all times after the change of the diet.

The reversal of the diets in the cross-over design in 1965 brought about a decrease of cholesterol in Hospital K and an increase in Hospital N, as expected. The difference of the cholesterol levels now reversed itself, though the magnitude of the difference was somewhat smaller in this second phase, namely, 35 mg vs. 50 mg.

Triglyceride and Lipid Phosphorus

Serum triglyceride and lipid phosphorus determinations showed that these lipid fractions were also lower in Hospital N where the diet had been changed. The differences, however, were smaller for these two lipid fractions than for cholesterol. Furthermore, the triglyceride values were characterized by a high coefficient of variation. Consequently, of the three serum lipid values cholesterol obviously was the best discriminator between the two subject groups ingesting different diets.

Adipose Tissue

The composition of animal adipose tissue is influenced by diet; that the same holds true in the human species has recently become evident. Human adipose tissue can be examined by the needle biopsy technique followed by gas-liquid chromatographic analysis of the fatty acid composition of the sample. Such studies also afford a useful check on the adherence to the diet and on its long-range effects, as the composition of the adipose tissue changes slowly.

Samples of subcutaneous adipose tissue were taken from a group of patients in each hospital near the end of the first part of the experiment. All these subjects had been in the hospital at least five years.

Figure 6 shows the approximate fatty acid composition of subcutaneous adipose tissue of subjects in the two hospitals. Great differences were found. The adipose tissue of the experimental group contained much more polyunsaturated fatty acids, mainly linoleic acid, and much less saturated acids. In this group the myristic* acid and the palmitic acid were also considerably lower. The stearic acid contents were practically identical in both hospitals as were the contents of oleic acid. A comparison of the fat composition of the diets indicated that the adipose tissue reflected the fatty acid composition of the diet.

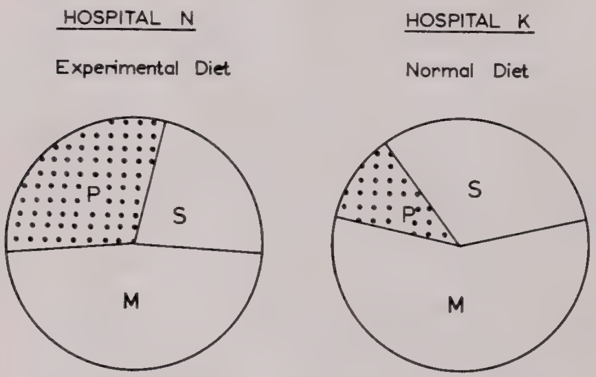

Fig. 6—Mean fatty acid compositions of adipose tissue of men in the two hospitals (S = saturated, M = monoethenoid, P = polyethenoid)

The changes of the adipose tissue after the reversal of diets are shown in Figure 7. Only two fatty acids, linoleic and myristic acids are included: the two with the greatest relative differences between the two groups. It is seen that two and a half years after the reversal of the diets, the fatty acid compositions had also become reversed, although not completely.

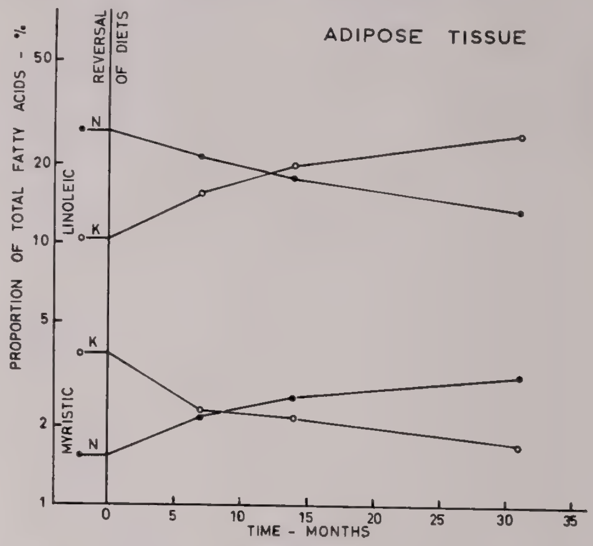

Fig. 7—Changes in linoleic and myristic acid contents of adipose tissue in the two hospitals after the reversal of the diets.

The Electrocardiogram

The assessment of incidence of coronary heart disease in these two groups was the most important aspect of our study. It was also the most difficult. Despite attempts to establish standardized systems of criteria for the diagnosis of coronary heart disease, no fully satisfactory system has been developed.

Furthermore, in our work we had to pay attention to special characteristics of our study groups, which consisted of psychiatric—mainly schizophrenic — patients. In such patients the response to painful stimuli is often considerably diminished; hence the symptomatology of coronary heart disease may be exceptional. The incidence of painless heart attacks is high and there is an almost complete absence of anginal syndrome. The incidence of sudden death is also high.

Chief reliance in this study was placed on electrocardiography. Electrocardiograms were taken from the study groups once a year. In the classification of records, the "Minnesota Code" was used. This system provides a method for a relatively objective classification of electrocardiographic findings. All records in this study were read and coded by the same member of the team and without knowledge from which hospital the tracing came.

---

*See Test Your Word Score Page 1213.

The incidence of electrocardiographic patterns presumably due to coronary heart disease, based on different criteria, is shown in Table 1. Two criteria having different levels of discriminative power and based directly on the Minnesota Code are shown, first, Q items and, second, Q, S-T and T items, combined into one category. Furthermore, a system of criteria used by Epstein in the Tecumseh Study is also included at two levels of discrimination.

The first column shows the number of patients initially free from the respective electrocardiographic sign; the second shows the number of patients developing the sign some time during the six-year period of observation. The third column shows the annual incidence rate per one thousand, and in the extreme right column we see the significance of the difference between hospitals determined by means of the X^2 test. The data presented in this table demonstrate that the incidence of electrocardiographic patterns presumably due to coronary heart disease was, by all these criteria, markedly and significantly lower in Hospital N. The difference between the hospitals in the incidence of changes was greatest when the more rigorous criteria were applied; but even the use of the milder criteria revealed significant differences.

We also have electrocardiogram data (Table 2) for the first two years after the reversal of the diets. The figures are too small to be conclusive, but they point in the expected direction.

Coronary Mortality

Coronary deaths have also been studied. For this three criteria were adopted: 1, sudden unexpected death for which no other cause was evident; 2, slower death with objective diagnostic evidence of coronary heart disease, such as typical electrocardiographic changes and increase in serum transaminase or other enzyme activity; or 3, death associated with autopsy findings of occluding or nearly occluding thrombi in coronary arteries or of recent myocardial infarction.

A comparison of mortality between the two hospitals indicates that while the non-coronary mortality figures were practically identical, the coronary mortality was lower in Hospital N. However, the mortality figures were too small to permit statistically valid conclusions.

Incidence of Coronary Heart Disease

Table 3 shows the total incidence of coronary heart disease diagnosed from electrocardiographic criteria and coronary death. The electrocardiographic criterion used was "probable coronary heart disease," Classes I and II, according to Epstein. This was a criterion of medium discrimination, which, we felt, was

closer to the true incidence than the stricter criteria based on Q patterns only.

Table 3 also shows that the incidence of coronary heart disease was significantly lower in Hospital N but does not reveal the true incidence of coronary heart disease in our study groups. Cases with angina as their only manifestation were missed, as its diagnosis in groups like ours would be very difficult. Furthermore, non-fatal attacks of myocardial infarction which did not develop electrocardiographic changes permanent enough to be detected at the next recording period (which may have taken place several months later after the event) were also missed. But these cases were probably not numerous.

For the purpose of this study, however, it was immaterial whether we diagnosed all new cases of coronary heart disease or only a certain fraction if it was equal in both hospitals.

Conclusion

Was the diet really responsible for the lower incidence of coronary heart disease in the experimental group? The design of our experiment deviated from the ideal in that the two study groups were not drawn from the same population by a random allocation. We have tried to assess their comparability with reference to a number of known risk factors such as age, prevalence of hypertension, smoking habits and the electrocardiographic status at entry to the study. The differences seem insufficient to account for the marked difference in the incidence of coronary heart disease. The only significant factor which reasonably explains the lower incidence in the experimental group is the cholesterol-lowering special diet; however, we prefer to regard this conclusion as preliminary, until more data from the second part of the experiment become available.

The Mind and Food

Worry and anger may bring about constipation due to the injury to the digestion system. Fears and worry may also produce nausea and other upsets, according to an announcement by the Academy of Medicine.

At mealtime we should observe good eating habits and try to remain tranquil and having pleasant thoughts. By eating slowly and thoroughly masticating our food we would greatly improve and help in the digestion of our food.

Ulcerated patients should beware of highly emotional states like anger, resentment, hostility, anxiety, worry and arguments, as these cause disorders of stomach activity.*

*Culinary Almanac, 1949.

Oddities

Mining-camp doctors encountered odd afflictions made worse by neglect. In 1867 Dr. Glick removed a 70-foot tapeworm from Luke Byrne, a Bear Gulch, Montana, miner after he had treated himself with purgatives, vermifuges, and whiskey until he was too weak to dig. Dr. Thomas Reece of Helena traveled to nearby Unionville to treat a man and his wife who were seriously ill. He inquired as to what they had eaten and was told ham. Taking the ham to his office, he placed it under his microscope and discovered trichinae in the fibers. Soon everybody in town filed in to look at the specimens. Sales of ham ceased in Helena, and the butchers threatened to run the doctor out of town.*

A Lipid Clinic

Preliminary Observations*

STEWART L. NUNN, M.D.†
JOHN L. JUERGENS, M.D.†
RALPH D. ELLEFSON, Ph.D.‡
KENNETH G. BERGE, M.D.†
Rochester, Minnesota

In the summer of 1967 a lipid clinic was started at the Mayo Clinic. Our colleagues in internal medicine referred patients to us with elevated values for plasma lipids, and we have now seen several hundred of them. Such a patient's lipid abnormality is classified by determinations of plasma cholesterol, triglyceride and lipoprotein. A dietary history is obtained, and factors such as intake of alcohol, family history, other pertinent diagnoses and laboratory findings, presence of xanthomatoses or atherosclerotic disease are also noted. The treatment is individualized and depends not only upon classification of the lipid disorder but upon the other features just mentioned.

Causes

The clinical application of lipidology is very different from the epidemiologic application. The first difference is that elevation of values for lipids suggests to the clinician a variety of possible causes for which he must search.

Hypercholesteremia

Hypercholesteremia in the presence of normal values for triglycerides, that is, hyperbetalipoproteinemia or Fredrickson's Type II lipid disorder,[1] is observed in three clinical settings. It may be associated with a very high dietary intake of saturated fats and cholesterol and sometimes with obesity; appropriate dietary counseling is likely to be helpful. Hypercholesteremia can be the result of a familial disorder in which there are predictable hereditary features. This form is only partially affected by diet, and even the use of a full range of drugs may not bring the content of cholesterol in the plasma to normal. Finally, hypercholesteremia can be secondary to specific diseases, such as myxedema or biliary cirrhosis.

Hypertriglyceridemia

There is another family of common lipid

---

*Presented at the Minnesota Symposium on Prevention in Cardiology, Rochester, Minnesota, May 2 and 3, 1968.

†Mayo Clinic and Mayo Foundation: Section of Medicine.

‡Mayo Clinic and Mayo Foundation: Section of Biochemistry.

disorders in which values for triglycerides are elevated and in which, to a lesser extent, those for cholesterol may be elevated. These disorders seem frequently to be linked with carbohydrate intolerance or an excessive intake of alcohol and with obesity; it is quite unlikely that excessive dietary fat alone is responsible for them. It has been shown that carbohydrates, and especially sugar, will cause an increase in endogenous triglycerides in susceptible patients.[2] By measuring only blood cholesterol, or by not understanding the fundamental metabolic difference between hypertriglyceridemia and hypercholesteremia, it is possible to elevate the patient's blood lipids still more by substituting sugar and other carbohydrates for fat in the diet.

Value of Classification

The clinician, therefore, needs a specific assay of the lipid abnormality if he is to treat the patient rationally and successfully. A patient with definite and reproducible hypercholesteremia might be optimally treated with only *one* of the following programs, depending on the cause of the increase in cholesterol and whether or not it is associated with endogenous hypertriglyceridemia:

> A fat-restricted diet; a sugar-restricted diet; reduction in weight; cessation of intake of alcohol; diet and cholestyramine; diet and clofibrate; diet and nicotinic acid; treatment of myxedema—or other disease to which the hyperlipidemia may be secondary.

Because of this diversity, individual classification is of value. The following preliminary data come from the analysis of records of 100 consecutive patients as well as from some follow-up information that was available at the time of study.

Distribution of Types

No patients who had Type I hyperlipidemia were seen. Roughly half had Type II, hyperbeta-lipoproteinemia (increased content of cholesterol with normal values for triglycerides). The remaining half represented problems of very low density lipoprotein (VLDL) excess (endogenous triglyceride excess); three patients had a typical broad-band, beta pattern (Type III); and 16 had a variant of this with very low density lipoprotein excess carried on a narrow beta band. Twenty-seven patients had typical prebeta-lipoprotein excess (Type IV); six had prebeta-lipoprotein excess plus chylomicronemia (Type V) and three patients had mixtures of beta and prebeta-lipoprotein excess.

Characteristics of Types

Some differences of the types are apparent in Table 1. Although the ranges in age are similar, the distribution according to sex tended more toward females in Type II disorders and toward males in the other types. Mild fasting hyperglycemia or abnormal results of tests of glucose tolerance were noted in about 40% of those with an excess of triglyceride, but in none of the patients with Type II disorder. Obesity was twice as common among those who had excess of triglyceride (Types III, IV and V) as compared to those in the Type II group.

TABLE I

Lipoproteinemia: Characteristics in 100 Patients*

Obesity, %	44	90	70	100

*Type I lipoproteinemia not encountered in this series.

Other areas of differences between patients with Type II (with normal values for triglycerides) and the types with increased triglycerides are seen in Table 2. Treatment by diet achieved roughly an average reduction of 15% in the content of cholesterol in all types; however, dietary treatment lowered values for triglycerides much more successfully than it did those for cholesterol. Whereas lipid values of only 12% of patients with the Type II disorder were restored to normal, roughly half of the patients who had excess of triglycerides (Types III, IV and V) became normal by means of dietary treatment alone.

Our experience leads us to believe that there are two basically different common lipid disorders. One group, comprising about one half, is characterized by hypercholesteremia with a normal content of triglycerides (Type II). The majority of patients who have the Type II disorder appear to have acquired their abnormality apparently because of inability to maintain normal values for lipid in the face of a high intake of saturated fats or cholesterol, or

*Type I lipoproteinemia not encountered in this series.

occasionally because of some specific disease such as myxedema. Some of the patients with this disorder have familial hypercholesteremia; one third of our group had a family history of lipid abnormality. The familial disorder is resistant to treatment and usually requires both dietary and drug therapy (nicotinic acid or cholestyramine). The "acquired" types are more easily controlled by means of dietary treatment alone, or by specific treatment in cases in which the disorder is secondary to diseases such as myxedema.

The other groups of lipid disorders (Types III, IV and V) are those of excess of endogenous triglyceride, carried as a very low density lipoprotein in several different locations on the lipoprotein strip—either on a narrow beta band, a broad beta band or in the prebeta position with occasional spillover into the chylomicron band. These groups appear to be peculiarly responsive to reduction in weight and to the intake of alcohol or sugar. In the instances in which dietary treatment does not suffice, drug treatment (clofibrate) usually is very effective.

WHAT'S
SO WEAK
ABOUT
THE WEAKER
SEX?

OFTEN... HER LOWER G. I. TRACT

Psycho-abdominal Distress: Frequently Female

Women aged 15 to 45 appear to be more prone than men to bloating, cramping pain of stress-related intestinal disturbances such as irritable or spastic colon.[1,2]

Frequently Recurrent

In the experience of many physicians, women are more likely to reappear time after time with repeated complaints of lower G.I. distress.

Requiring Definitive Therapy

Often needed is therapy adequate to control both the somatic and the emotional components of psycho-abdominal complaints.

Definitive Dual Therapy

'Milpath' contains a proven synthetic anticholinergic useful for relieving hypermotility, spasm, and hypersecretion of the gastrointestinal tract.

In addition, 'Milpath' provides a time-tested tranquilizer for mild but effective anti-anxiety action.

With Flexible Dosage

- 'Milpath'-400 (meprobamate 400 mg. + tridihexethyl chloride 25 mg.) Usual adult dose: 1 tablet *t.i.d.* and 2 at bedtime.
- **When less tranquilization is required: 'Milpath'-200 (meprobamate 200 mg. + tridihexethyl chloride 25 mg.)**

Wallace Pharmaceuticals/Cranbury, N. J. 08512

gently but firmly

MILPATH®

(meprobamate + tridihexethyl chloride)

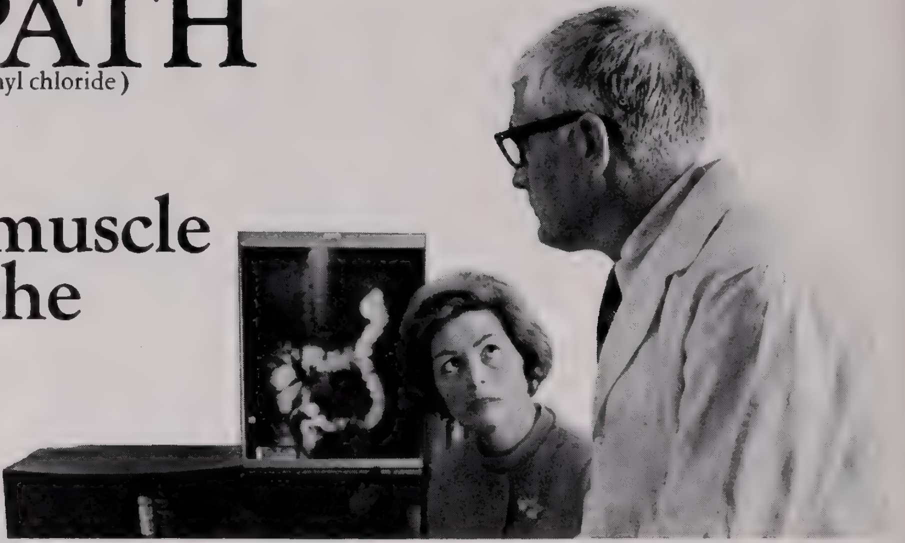
relaxes smooth muscle and psyche

Please see the following page for brief summary of prescribing information.

Gently but firmly MILPATH®

(meprobamate + tridihexethyl chloride)

Relaxes smooth muscle and psyche



Usual Adult Dosage

One 'Milpath'-400 tablet, three times a day at mealtimes, and two at bedtime. For greater anticholinergic effect, two 'Milpath'-200 tablets, three times a day at mealtimes and two at bedtime. Doses of meprobamate above 2400 mg. daily not recommended.

Indications

Useful in organic and functional disorders with hypersecretion and hypermotility of G.I. tract, especially when accompanied by anxiety, neurosis, or tension states. Should be used as an adjunct to all other therapeutic measures.

Contraindications

Tridihexethyl chloride: Urinary bladder-neck obstructions, e.g., prostatic obstruction due to hypertrophy; pyloric obstructions because of reduced motility and tonus: organic cardiospasm (megaesophagus); glaucoma; possibly in stenosing gastric or duodenal ulcers with significant gastric retention.

Meprobamate: Previous allergic or idiosyncratic reactions to meprobamate.

Precautions

Tridihexethyl chloride: Use cautiously in elderly males (possible prostatic hypertrophy).

Meprobamate: Carefully supervise dose and amounts prescribed. Consider possible dependence or habituation (reported occasionally after excessive use), particularly in severe psychoneurotics, alcoholics, ex-addicts. Withdraw gradually (one or two weeks) after excessive dosage for weeks or months to avoid recurrence of pre-existing symptoms (e.g., anxiety, anorexia, insomnia) or withdrawal reactions (e.g., vomiting, ataxia, tremors, muscle twitching; rarely, epileptiform seizures, more likely in those with CNS damage or latent convulsive disorders). If drowsiness or visual disturbance occurs, reduce dose and advise against activity requiring alertness (driving, machinery operation). Effects of excess alcohol may be increased. Grand mal seizures possible in persons with both petit and grand mal. Prescribe cautiously in small amounts to patients with suicidal tendencies. Prescribe with caution to patients with known sensitivity to compounds of similar chemical structure, e.g., carisoprodol.

Side Effects

The following side effects of components may occur with 'Milpath'.

Tridihexethyl chloride: Severe effects rare on recommended dosage. Anticholinergic effects: dry mouth (fairly frequent at oral doses of 100 mg.), constipation or "bloated" feeling. Possible: tachycardia, dilation of pupils, increased ocular tension, weakness, nausea, vomiting, headache, drowsiness, urinary hesitancy or retention, dizziness.

Meprobamate: Drowsiness, sometimes with ataxia, usually controlled by decreasing dosage, occasionally with aid of central stimulants (e.g., amphetamine). Rarely, allergic or idiosyncratic reactions (usually after one to four doses); in mild form: itchy, urticarial or erythematous, maculopapular rash, generalized or confined to groin. Acute nonthrombocytopenic purpura with cutaneous petechiae, ecchymoses, peripheral edema and fever, transient leukopenia, and one fatal bullous dermatitis (after meprobamate and prednisolone) reported. More severe, very rare hypersensitivity: fever, chills, fainting spells, angioneurotic edema, bronchial spasms, hypotensive crises (one fatal), anuria, anaphylaxis, stomatitis and proctitis. Treat symptomatically (e.g., epinephrine, antihistamines, possibly hydrocortisone); stop and do not restart the drug. Isolated agranulocytosis, thrombocytopenic purpura, one fatal aplastic anemia reported, but only in presence of known toxic drugs, porphyric symptoms reported but relationship not established. Fast EEG activity, usually after excessive dosage. Impairment of visual accommodation reported by one observer. Fixed drug eruption with meprobamate and cross reaction to carisoprodol reported.

Suicidal attempts may produce drowsiness, lethargy, stupor, ataxia, coma, shock, vasomotor and respiratory collapse, and death. Excessive dosage has led rapidly to sleep, then reduction of vital signs to basal levels. Empty stomach, and if respiration becomes very shallow and slow, cautiously give CNS stimulants (e.g., caffeine, pentylenetetrazol, amphetamine); also pressor amines if indicated.

Supplied

In two strengths:

'Milpath'-400: Yellow, scored tablets.

'Milpath'-200: Yellow, coated tablets.

Before prescribing, consult package circular.

A Practical, Palatable Way of Eating[*]

ANCEL KEYS, Ph.D.[†]
Minneapolis, Minnesota

ANY DISCUSSION of efforts to prevent coronary heart disease must consider dietary management because there is so much reason to suspect that the current ordinary American diet contributes substantially to the development of atherosclerosis and its complications, notably coronary heart disease. This idea is hotly debated by representatives of certain food industries and there is as yet no guarantee that changing the diet in middle-age or older will reduce the likelihood of future heart attacks. Nevertheless, control of the diet can lower the serum cholesterol concentration; and a great many Americans, including physicians, are interested in a practical, palatable diet that will lower the cholesterol level and, perhaps, diminish the risk of future heart attacks. From the response to invitations to take part in the National Diet-Heart Study it can be estimated that something like 10 per cent of the middle-aged population in U.S. metropolitan areas are sufficiently interested to volunteer for dietary trials that would involve much inconvenience and no promise of any real benefit.[1]

Incidence of Coronary Heart Disease

Table 1 summarizes the overall average experience of prospective studies on men in Framingham (Massachusetts), Albany (New York), and Minneapolis-St. Paul (Minnesota). For middle-aged American men, apparently healthy at the entry examination, the risk of developing coronary heart disease within a few years rises steeply with increasing serum cholesterol concentration. If the relative incidence rate for men with entry cholesterol values under 200 is taken as 100, the rate for men with values of 250 is about 285, almost three times greater. The relative incidence rate for men otherwise comparable rises as about the cube, the third power, of the serum cholesterol value and there is no break or "critical level." In regard to serum cholesterol concentration: the lower the better.[2]

---

[*] Presented at the Minnesota Symposium on Prevention in Cardiology, May 2-3, 1968 in Rochester, Minnesota.

[†] Professor and Director Laboratory of Physiological Hygiene, University of Minnesota.

TABLE I

Relative incidence rate of coronary heart disease of U.S. white men classified by entry level of serum cholesterol. Average of data on men in Framingham, Mass. (courtesy of Dr. W. B. Kannel), men in Albany, N. Y. (courtesy of Dr. J. T. Doyle) and men in Minneapolis-St. Paul (Keys et al. 1963 Circulation *28*, 381). The age- and area-specific rate for all men regardless of cholesterol level is taken as 100.

Chol., mg/dl	Under 200	200-219	220-239	240-259	260+
Coronary heart disease incidence	47	60	93	134	202

Since no penalty from other disease or other disadvantage is associated with cholesterol levels lower than the current average in the United States, the inference is that a large fraction of the whole American population should be candidates for serum cholesterol control if safe and otherwise acceptable means are available. Roughly, it may be estimated that for Americans aged 40 or more the general average serum cholesterol value is between 230 and 240. Such values may be considered "normal" according to some definitions, but among middle-aged men those "normal" values are associated with about twice the coronary death rate associated with serum cholesterol values 15 per cent lower. Since something like one third of middle-aged white Americans have serum cholesterol values over 240, it could be suggested that a third of our adult population would benefit from serum cholesterol control. Or perhaps the specification should be for the adult population up to age 65 or so, because the influence of serum cholesterol as a risk factor diminishes with age and may be trivial in the sixties and beyond.

Approaches To Cholesterol Control

Effect of Duration & Concentration

All students of the cholesterol-atherosclerosis question agree that whatever may be the action of cholesterol in the blood plasma, the net result must be a function of concentration times the duration of that concentration. Not only is that conclusion consistent with the evidence that cholesterol control that begins only late in life must have less value than lifelong control; it also indicates that short-period reductions of serum cholesterol level are of little or no use. So whatever method is proposed for serum cholesterol, it can have little value if it operates only temporarily.

Surgical Approach

The surgical approach involves shortening the length of the small intestine; the serum cholesterol then falls promptly and stays reduced when operation is done properly. This drastic intervention may be justifiable for some rare individuals but obviously cannot be seriously considered for large-scale application. The drug approach is less readily dismissed.

Drugs

Several drugs—atromid S ("CPIB"), nicotinic acid, thyroid, sex hormones and some resins that sequester cholesterol or bile salts in the intestine—will lower serum cholesterol in almost all people when given in suitable doses. Neomycin taken orally has some cholesterol-lowering effect. With the exception of atromid S, all of the effective preparations have some unpleasant or worrisome side effects; even atromid S may not be devoid of other actions, as was originally claimed. But granting that the side effects of one or more of these drugs are tolerable to many people and true toxicity is not obviously a serious problem, it scarcely seems reasonable to propose that a large proportion of the whole population be dosed with drugs daily throughout life. And yet without continuous and indefinitely prolonged use there can be little prospect of even potential preventive benefit. Conceivably, lifelong drug dosage may have a place for use with some patients but not for the general public.

Diet

Exactly the same stipulation holds for dietary management. No endorsement can be given to short dietary trials, even if the diet does have some temporary effect. To be truly effective, dietary management must aim at establishing a suitable dietary way of life. But this stipulation is not a cause for concern in the case of the diet. The habitual dietary practices of millions of people over many generations can be described as a "suitable dietary way of life" in this respect. Our own prolonged studies on such populations in Greece, parts of

Yugoslavia and parts of Italy indicate no health hazards of any kind from lifelong subsistence on suitably chosen diets that maintain the serum cholesterol level 15 to 25 per cent lower than the U.S. average.

Serum Cholesterol Changes From Known Dietary Changes

Influence of Polyunsaturated Fatty Acids

The average effect of the diet on the serum cholesterol concentration of American men is known from many controlled experiments, especially in mental hospitals and in prisons where metabolic ward conditions can be maintained for prolonged periods.[3-6] Table 2 considers the effect of differences in the percentage of total calories provided by saturated and by polyunsaturated fatty acids in the diet. Monounsaturated fatty acids in the diet, notably oleic acid, have no effect on serum cholesterol concentration when they are exchanged for equal calories of starch in the diet. Briefly, as Table 2 indicates, saturated fatty acids in the diet raise the serum cholesterol level while polyunsaturated fatty acids have an opposite but weaker effect; roughly two grams of linoleic acid would be needed to balance the effect of one gram of palmitic acid. To counter the effect of an ounce of butterfat in the diet it would be necessary to add about two ounces of corn oil to the diet which, of course, poses a problem of total calories and obesity.

TABLE 2

Average change of serum cholesterol (CHOL, mg/dl) in response to changed percentage of dietary calories from saturated (S) and poly-unsaturated (P) fatty acids:

$CHOL_2\text{-}CHO_1 = 2.7\ (S_2\text{-}S_1) - 1.3\ (P_2\text{-}P_1)$

DIET	S	P	CHOL
1) U.S. average	17	5	230
2) A recommended type	8	10	199
3) 2) - 1)	–9	5	–31

Actually, it is an over-simplification to consider all saturated fatty acids as equivalent. The shorter-chain saturated fatty acids, those with fewer than 12 carbon atoms in the chain, have no more effect than equal calories of starch in the diet. The same is true of the 18-carbon saturate, stearic acid, and probably of saturated acids with more than 18 carbons in the chain. In other words, the cholesterol-raising effect of saturated fatty acids is practically restricted to those with 12 to 17 carbon atoms. Accordingly, the chief dietary "enemies" are lauric* (12C), myristic (14C) and palmitic (16C) acids. The recent discovery of the lack of serum cholesterol effect of stearic acid does not do much to alter the calculation for predicted effects of most ordinary diets, but it does mean that chocolate is no longer on the forbidden list of the cholesterol-watcher. The fat in cocoa and chocolate is highly saturated; but stearic acid makes up the great bulk of the saturates, and trials with large quantities of cocoa butter in the diet show no cholesterol-promoting effect.[7,8]

Exogenous Cholesterol Influence

Besides fatty acids, it is necessary to consider exogenous cholesterol supplied in the diet. Again, many controlled experiments on men in prisons and hospitals have shown the effect on serum cholesterol of changes in the dietary cholesterol, all other factors being equal.[5,9] If the dietary cholesterol is expressed in mg. per 1000 calories, its average effect on the serum level is proportional to the square root of that dietary cholesterol concentration, as shown in Table 3. On a diet similar to the U.S. average in regard to fats and cholesterol, the average for middle-aged men is a serum value of about 230, as noted above. If all the cholesterol in the diet could be removed but the diet left otherwise unaltered, the average serum level would be about 207; that is to say, the concentration would fall about 10 per cent. But zero-cholesterol diets are impossible to provide for free-living people. A practical diet sharply restricted in cholesterol still contains something like 100 mg. of cholesterol per 1,000 calories. Change from an ordinary U.S. diet to a diet so low in cholesterol but otherwise unchanged produces an average fall of only about 3 to 4 per cent in the serum concentration. Conversely, the addition of two egg yolks to the daily diet of the average middle-aged man, which would mean an addition of about 200 mg. of cholesterol per 1000 calories, to make a total of about 425 mg/1000 calories, does not have a large effect. On the average that dietary change causes a rise of less than three per cent in the serum cholesterol. The upshot is that dietary cholesterol has some effect in man, but the effect of cholesterol restriction in practical diets is very limited.

---

*See Test Your Word Score Page 1213.

TABLE 3

Let Z^2 = dietary cholesterol, mg per 1000 calories, and CHOL = serum cholesterol, mg/dl. Then the change from diet 1 to diet 2 produces the average serum response: $CHOL_2 - CHOL_1 = 1.5\ (Z_2-Z_1)$

ITEM	Z^2	Z	CHOL
1) A common U.S. diet	225	15	230
2) A low-cholesterol diet	100	10	222
3) Zero-cholesterol "	0	0	207
4) A high-cholesterol " (extra 2 eggs/day)	425	21	236

Individual "Cholesterolstat" Setting

The average effects of diets indicated in Tables 2 and 3 relate to average men. But individuals differ intrinsically in their cholesterol metabolism; their "cholesterolstats" have different settings, so to speak. With few exceptions, the higher the intrinsic level of the individual, the more sensitive is the serum cholesterol concentration to the diet and, apparently, also to drugs. In general, persons with very high serum values on an ordinary U.S. diet will show much bigger responses to dietary change than indicated in Tables 2 and 3.

Besides dietary fats and cholesterol, some other dietary items should be considered. Variations in proteins, vitamins and minerals over the range of practical and generally acceptable diets have no significant effects, nor is there any alteration in the serum level when tolerable exchanges are made among sugars and starches. But some complex carbohydrates—pectin and some mucilaginous gums—have a modest cholesterol-lowering effect when they are added to the diet.[10,11] A specific cholesterol-lowering effect of beans and other leguminous seeds in the diet is probably also due to complex carbohydrates.[12]

Practicalities

The first requirement in translating the results from experiments into menus and recipes is to ensure safety. We must be absolutely sure that new diets to be recommended for possible coronary prevention carry no possibility of producing nutritional deficiencies or other dangerous or merely unpleasant physiological or metabolic states. With insistence on a mixed diet of a wide variety of natural foods and recommendation for abundant use of skim milk, leafy and colored vegetables, and fruits, no question of medical acceptability and safety can arise.

Reduce Saturated Fatty Acids

The first requirement for the cholesterol-lowering diet is a sharp reduction in the saturated fatty acids or, to be more specific, lauric, myristic and palmitic acids. In practical terms this means the elimination, or at least severe restriction, of fatty meats, butter, cream, ordinary ice cream, whole milk, lard and highly hydrogenated shortenings, and many commercial pastries. Suitable vegetable oils—corn, sunflower, cottonseed, soybean, safflower, according to preference and availability—should be used for salads and all cooking. Olive oil, though not high in linoleic acid, is low in saturates and is not forbidden for those who like the flavor.

"Fatty meats" include most pork and most of the "better" (i.e., more expensive) grades of beef currently sold in the United States. However, the watchful shopper can find truly lean beef and pork today; the meat industry is responding to the demand of the times. But even apparently lean beef and pork often prove to contain so much saturated fatty acid that small portions, or substitution of other main-dish foodstuffs, are advisable. Substitution is easy. Chicken and turkey are cheap and much more suitable for the cholesterol-watcher. Fish is not so cheap but it is even more suitable than fowl.

There is much misunderstanding about shellfish. Oysters, lobsters, etc., though very low in saturated fatty acids, worry some people because they may be rather high in exogenous cholesterol. But, as noted above, unless the diet can be reduced to nearly zero cholesterol, the effect on serum cholesterol of moderate variations in the dietary cholesterol intake is very small. The ordinary cholesterol-watcher is not forbidden to have a few whole eggs a week, and there is even less to be concerned about in the consumption of shellfish several times a week.

An abundance of fruits and leafy vegetables and generous use of beans, peas, and their relatives as meat substitutes will also help keep the serum cholesterol down. All of the foregoing points are elaborated in detail, with numerous recipes, menus and cooking hints, in a number of books suitable for the general public.[13-19] The net result is that with the help of such books and a little experience the cholesterol-watcher can have unlimited gustatory pleasure with little effort and an actual saving of money.

*Calories**

The substitution of polyunsaturated for saturated fatty acids in the diet is useful, but there has been too much propaganda about the virtue of certain vegetable oils than is warranted by the facts. Simply *adding* corn or other oil to the diet makes no sense; calorie excess raises the serum cholesterol level as well as promotes obesity. No epidemiological evidence can be offered to support the idea of "dosing" with one or another oil. The ordinary current U.S. diet provides some 4 to 7 per cent of total calories from linoleic and other polyunsaturated fatty acids. Natural populations have not been found anywhere who have appreciably higher intakes of the polyunsaturated fatty acids. In our own worldwide studies we find no lack of examples of populations whose serum cholesterol levels and frequencies of coronary heart disease are admirably low compared to the situation in the United States. Not one of those populations has a higher intake of polyunsaturated fatty acids than the ordinary U.S. diet; but the intake of saturated fatty acids is invariably low.

Barometric Pressure and Disease

South winds induce dullness of hearing, dimness of visions, heaviness of the head, torpor, and languor; when these prevail, such symptoms occur in diseases. But if the north wind prevail, coughs, affections of the throat, hardness of the bowels, dysuria attended with rigors, and pains of the sides and breast occur. When this wind prevails, all such symptoms may be expected in diseases.*

***Hippocrates.**

Edward N. Peterson, M.D.

The cover photo was taken in an alpine meadow on the west side of Mt. Ranier in Washington and it is particularly beautiful when the mountain flowers are in bloom in August.

Doctor Peterson spent eight years in Oregon; four and one-half in private practice and three and one-half in academic medicine on the full-time faculty of the University of Oregon Medical School. An outstanding professional opportunity was offered to him in the Department of Obstetrics and Gynecology at the University of Pittsburgh School of Medicine in July, 1968. His subspecialty is cardiovascular physiology of pregnancy and his main research interest is in maternal blood flow changes as related to reproductive failure in women.

While living in the West he and his family developed the hobby of camping in the primitive areas of the Cascade Range. The children by 1967 had matured enough to go on backpacking trips and it was then they chose to hike the trails on Mt. Ranier.

During one of these hiking trips that summer Dr. Peterson noticed the pink glow and reflection on his way to a spring for water and immediately ran back for the camera. *Seconds* afterward the picture was taken the color had faded and the mountain was dark.

Dr. Peterson grew up in Virginia, Minnesota, where his father is a practicing general surgeon. His guidance and example led Dr. Peterson and his brother, Dr. Charles A. Peterson of Minneapolis to attend the University of Minnesota Medical School from which Dr. Ed. Peterson was graduated in 1954.

He and his family now live in suburban Pittsburgh in an area called Fox Chapel. All four children attend public school and their mother, freed of daily homemaking responsibilities, has also returned to school. Mrs. Peterson graduated from the University of Minnesota School of Nursing in 1953 and is now completing studies in the University of Pittsburgh Graduate School of Public Health, working for a master's degree in Maternal and Child Health.

For Oyntment iuyce of Onyons is assigned,
To heads whose hair fals faster than it growes:
If Onyons cannot helpe in such mishap,
A man must get him a Gregorian cap.*

—**Regimen Sanitatis Salerni**

---

*A wig of a style designed by a barber named Gregory.

Editor's note: Succinct and impish advice to the bald: if a scalp tonic of onion juice fails to grow hair, a wig is the only alternative and the last resort. It seems that in ten centuries Medicine has not been able to improve on onion juice as a trichotropic agent.

Overweight and Obesity*

The Associated Cardiovascular Risk

CARL C. SELTZER, Ph.D.†
Boston, Massachusetts

THE TERMS OVERWEIGHT and obesity are not necessarily synonymous.

Overweight refers to body weight in excess of a standard, whether the standard be average, ideal, or desirable weight, but it may bear little relation to the person's fat status. *Obesity*, on the other hand, refers to the condition of fatness or to an excess amount of adipose tissue. Excess weight over a standard does not tell us whether it represents fat, bone, muscle, fluid, or the relative contributions of these components. What part of the weight can be charged to the fatty component? And since there is no universal agreement on the degree of overweight which constitutes a presumption of obesity, some consider a deviation of even 10% above average or desirable weight as constituting such a presumption; others use 15% or 20% as the outside of normality, and still others use an even higher percentage. Accordingly, not all overweight persons are obese, and conversely some persons can be obese without being markedly overweight. It depends on the amount of overweight and the base line of the abstract value, and whether the overweight is in reality fat.

Height-Weight Tables

The value of the height-weight tables popularized by life insurance companies is subject to severe limitations;[1,2] the derivation of the degree of obesity from these tables can be quite misleading. This is particularly true in the case of the overweight designations based on the "desirable" weight tables of the Metropolitan Life Insurance Company, since these arbitrary tables give weights for height far below the average weights for height of the general population. If degree of fatness is sought, then the criteria of obesity should be based on actual

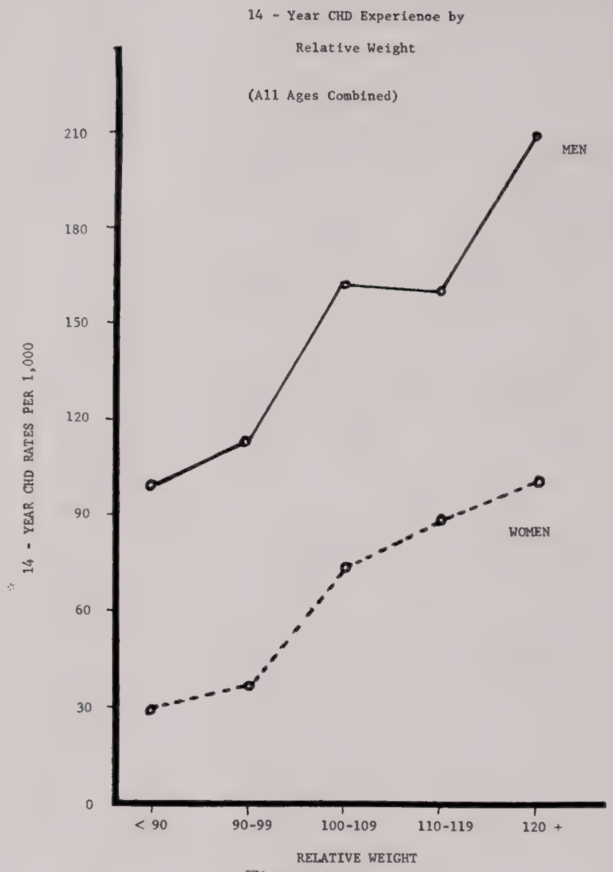

Figure 1

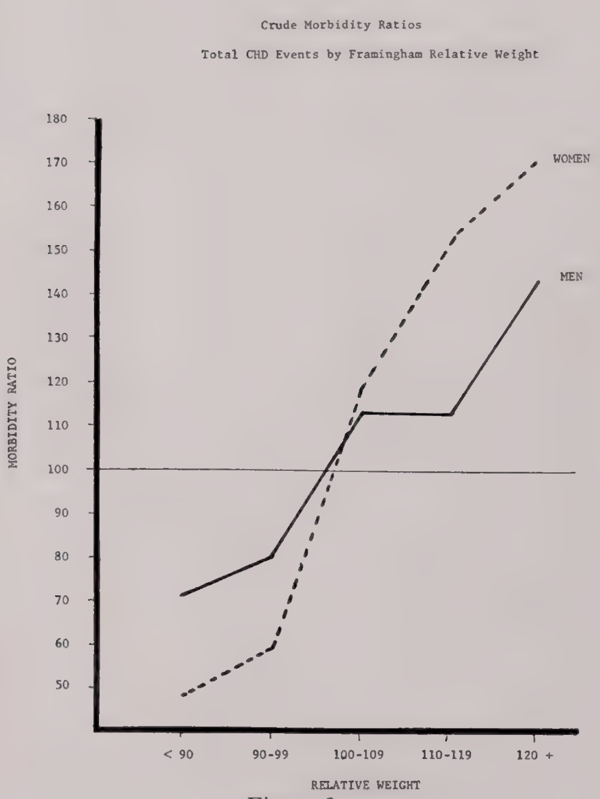

Figure 2

measurement of fatness and not on inference of fatness.

Skinfold Measurements

The appearance of the naked patient is the usual basis for the diagnosis of obesity by the experienced clinician and, as a qualitative guide, is usually reliable. But when a quantitative estimate is desired, skinfold measurement is recommended. For the clinic and for large-scale surveys, it has been shown that skinfold measurements, particularly those of the triceps and subscapular skinfolds, are relatively simple and practical measures of adiposity.[3]

Fatness and Cardiovascular Disease

To define overweight and obesity is important for several reasons. First, by far the largest amount of information bearing on the relationship between obesity and cardiovascular disease is based on overweight designations. It is only over the last decade or so that data have been collected on the relationship between direct measurement of fatness and cardiovascular disease, through the use of skinfold values. Secondly, in these studies, there is no uniformity in the degree of overweight designations or in the base line from which the overweight percentages have been computed. They vary from 10% up to even 30% relative weights. Thirdly, even when skinfold measurements are used, such measurements have not been taken in the context of body build types. Accordingly, even while there is at present a wealth of information bearing on "fatness" and cardiovascular disease, we do not know for sure what part of the effect observed is the result of fatness or of body build type. Thus, we do not know whether a moderate amount of adipose tissue in a dominant ectomorph (linear, attenuated body build type) is as deleterious or lethal a factor as a considerably greater quantity of fat in a dominant mesomorph (heavily boned and muscled in individual) or a still greater excess in a dominant endomorph.

Mortality

Insurance company studies indicate that overweight is associated with increased mortality, particularly from cardiovascular diseases. The monumental study of the Society of Actuaries pertaining to build and blood pressure found progressively higher mortality rates from coronary heart disease with increasing degrees of overweight.[4] Dublin and Marks of the Metropolitan Life Insurance Company show statistically that overweight persons who reduce and stay reduced may substantially increase their life expectancy.[5]

Clinical studies, however, have produced conflicting reports on the role of overweight or obesity in coronary heart disease.[6,7,8,9,13] In some instances, only extreme obesity was associated with an increased rate of development of coronary heart disease, though most epidemiological studies show a relationship between overweight or obesity and the morbidity and mortality from coronary heart disease.[10,11,12]

Cholesterol and Hypertension

Keys and Stamler found that overweight or body fatness did not appear to be an important risk factor *except* insofar as these conditions were related to high serum cholesterol or to hypertension, hyperlipidemia, and diabetes mellitus, except when obesity is very gross.[14]

Conflicting Findings

These conflicting results may be due to a lack of consistency in the criteria of overweight or obesity, to differences in the nature of the populations studied, such as geography, diet, physical activity, body build, habits, "style of life," or to associated diseases and differential cardiovascular risk factors such as hypertension and hyperlipidemia. These factors must be held constant in the analysis. Among the epidemiological investigations, some are prevalence studies and others are long-term prospective studies giving incidence rates.

We believe, as has been shown by the Framingham Heart Study, that the most important reason for the failure of controlled clinical and epidemiological studies to give consistent results has been the failure of these studies to relate overweight or obesity to each specific overt manifestation of coronary heart disease[10]; conflicting reports have arisen from the differences in the proportion of angina pectoris, sudden death, and myocardial infarction included in the cases reported. For 14

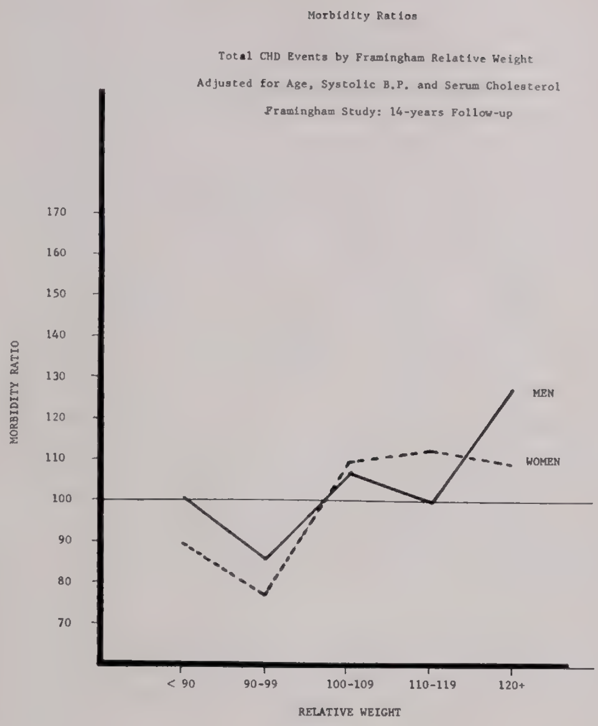

Figure 3

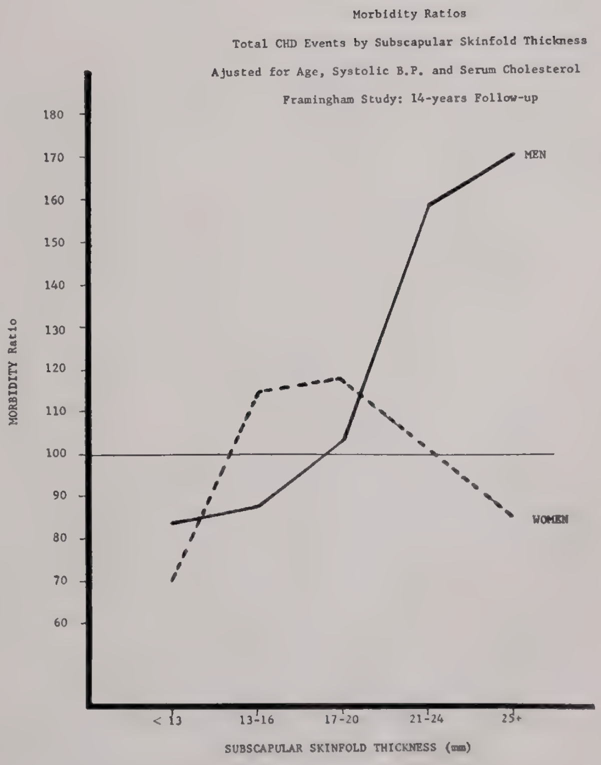

Figure 4

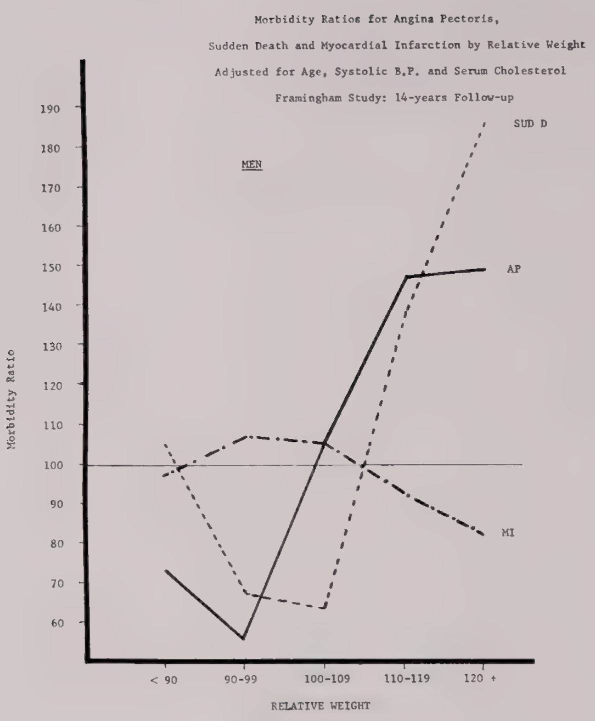

Figure 5

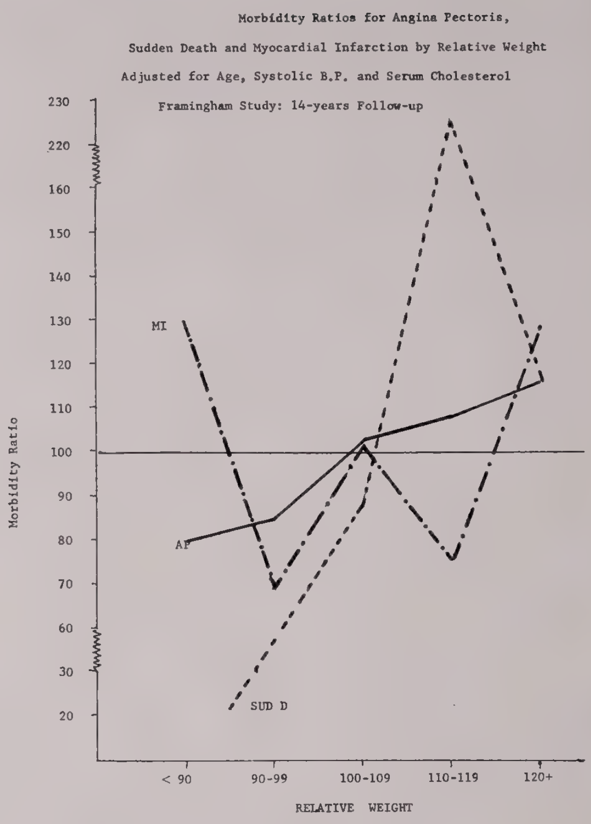

Figure 6

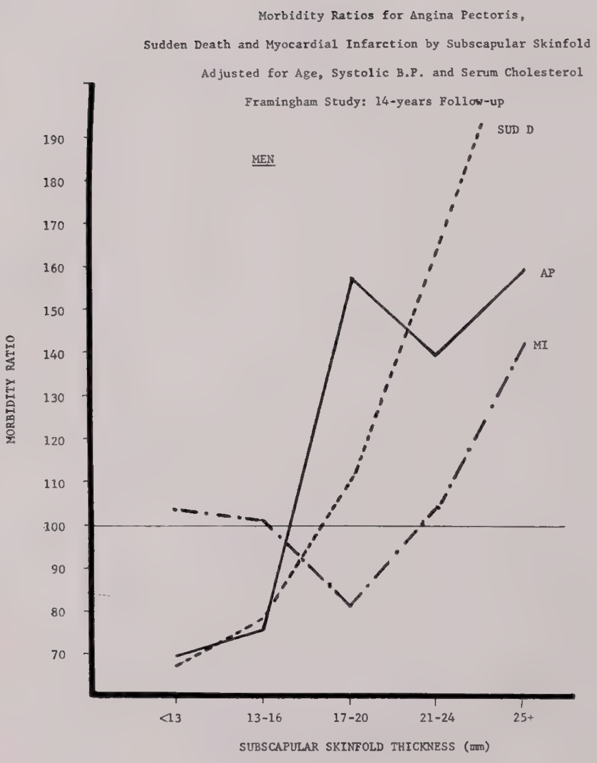

Figure 7

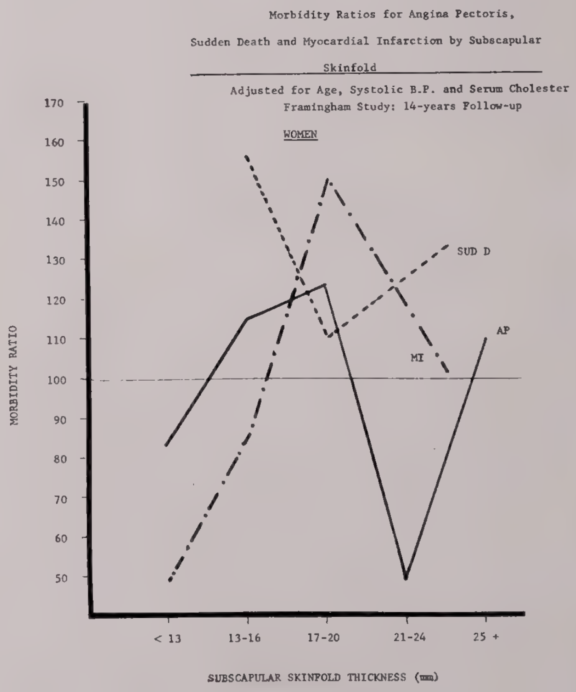

Figure 8

years men and women between the ages of 30 and 62 years have been measured by both relative weight and skinfold thickness. Those taken at the initial examination show that the clinical manifestations of coronary heart disease are roughly proportional to the degree of overweight and adiposity on entry (Figures 1 and 2). However, when total coronary heart disease was broken down into its specific manifestations it was found that, while obesity was clearly related to angina pectoris and sudden death, it was not significantly related to myocardial infarction (Figures 3 to 8), even when adjustments were made for age, hypertension, cholesterol level and diabetes. When these latter factors were present, the effect of adiposity on these coronary heart disease events was more pronounced, though in women there was no independent effect of obesity when adjustments were made for age, hypertension, cholesterol level and diabetes. But when these atherogenic factors are present, obesity in females is related to angina pectoris and sudden death but not to myocardial infarction.

Furthermore, it was noted that while overweight persons tended to develop more hypertension, lipid abnormalities and diabetes—conditions usually associated with an early development of atherosclerosis—autopsy studies on subjects who had participated in the Framingham Study[15] showed no significant correlation of relative weight with the extent of atherosclerotic disease in the coronary circulation (Table 1). Heart weight, however, was clearly related to the degree of adiposity (Table 2).

Conclusions

In summary, the seemingly contradictory findings of insurance, clinical, and epidemiological investigations appear to be explained. Most of them are probably correct in the context given but are not fully explicit and revealing. This is because the results have been almost universally given in terms of the rubric* of total coronary heart disease morbidity or mortality. But when the rubric is broken down into the various manifestations of coronary heart disease such as angina pectoris, sudden death, and myocardial infarction, the inconsistencies become clarified.

Our best present knowledge would indicate that overweight or obesity is a serious cardiovascular health hazard and a potent force for morbidity and mortality from coronary heart disease. In both sexes, the risk of angina pectoris and sudden death appear to be roughly proportional to the degree of obesity, and the very grossly obese have an unusual propensity to sudden unexpected deaths. Obesity, however, does not appear to be a significant factor predisposing to myocardial infarction. In men, the risk of angina pectoris and sudden death is apparently independent of associated atherogenic factors such as hypertension, higher cholestrol levels and diabetes; but when these factors are present the deleterious effect of obesity is considerably increased. In women, however, there is no independent effect of obesity in connection with angina pectoris and sudden death, but there is a strong relationship with obesity when it is present in association with hypertension, higher cholesterol levels and diabetes.

It would appear that obesity may act as a precipitating cause in producing angina pectoris and sudden death, possibly owing to the increased work load imposed on the heart. Excess adiposity, on the other hand, does not appear to make a significant contribution to the atherosclerotic process and seems to be relatively independent of myocardial infarction.

With respect to coronary heart disease prevention, avoidance of obesity is indicated because of its association with the development of atherogenic traits such as hypertension, lipid abnormalities and diabetes. Weight reduction in persons with these atherogenic traits improves these factors and probably delays the onset of symptomatic disease. Weight reduction in obese persons improves exercise tolerance and reduces risk of initial or subsequent coronary heart disease events.

My concluding point has to do with body build type considered apart from adiposity. What is interesting in the Framingham data is that, in virtually every single instance, those ectomorph type persons with the lowest relative weight values, those under 100 pounds, showed the lowest risk of total coronary heart disease, angina pectoris, sudden death and myocardial infarction. In addition, they exhibited fewer atherosclerotic processes and smaller heart size. If this is so, then it would appear that ectomorphic physical types are less prone to manifestations of coronary heart disease events of all forms than other body build types. This reinforces our contention that body build types and fatness should be studied conjointly.

Acknowledgment

I wish to express my appreciation to Dr. William B. Kannel, Director of the Framingham Heart Study, for providing me with much of the data presented and for permission for their use.

Elevated Blood Sugar*

The Associated Cardiovascular Risk

FREDERICK H. EPSTEIN, M.D.†
Ann Arbor, Michigan

THE FREQUENT COEXISTENCE of diabetes and coronary heart disease has been known at least since the early 1920s. In 1941 Woodyatt stated that it is the *mild* form of diabetes which appears to be particularly associated with coronary disease.[1] The argument may be taken one step further to the proposition that the association is not so much with diabetes but with decreased glucose tolerance, considering glucose tolerance as a continuous variable, like blood pressure or the serum cholesterol level.

Abnormal Glucose Tolerance

Data from clinical studies based on oral glucose tolerance tests, as summarized by Wahlberg,[2] indicate that the proportion of patients with coronary disease who have abnormal tests differs from study to study being 61 per cent on an average. The frequency of abnormal results is much higher than one would expect in the general population.

Gorlin and his group in Boston have demonstrated latent diabetes in a large proportion of patients with coronary disease as demonstrated by cinearteriography.[3] The results of a similar study[4] in 27 patients with abnormal coronary arteriograms disclosed eighteen with abnormal glucose or cortisone-glucose tolerance tests, and the majority of these patients showed multiple metabolic abnormalities. Of the seven patients who had three abnormalities, three were classified as Type IV and the remainder as Type II by the lipoprotein nomenclature of Fredrickson. Hatch and co-workers found abnormal glucose or cortisone-glucose tolerance tests among young men with coronary heart disease[5] 6.7 times more often than expected. Tzagournis and associates[6] similarly demonstrated abnormal glucose tolerance in patients with coronary disease and reported that this phenomenon was accompanied by an increase in immuno-reactive insulin levels.

†Professor, School of Public Health, Department of Epidemiology, University of Michigan.

Results from several[7,8,9,10,11] epidemiological investigations strongly support these clinical observations.

This array of evidence makes a strong case for regarding elevated blood sugar as a risk factor in the development of coronary heart disease, even though most of the evidence is not based on prospective observations. The question, therefore, arises whether glucose tolerance is correlated with any of the other established or suspected risk factors.

Elevated Blood Pressure

The only other risk factor for which there is definite evidence of a strong association with glucose tolerance is blood pressure. Clinically, the association between hypertension and diabetes has been recognized for a long time. Indeed, Pell and d'Alonzo,[12] and Stamler[13] report that the association between diabetes and coronary disease has no direct significance since non-hypertensive diabetics showed no increased risk. In the Tecumseh Study hypertension and hyperglycemia are also associated, but the coexistence does not account for the relationship between hyperglycemia and coronary disease.[7] More recently, however, Conn[14] has suggested that primary aldosteronism might be a common denominator.

Serum Lipids

There is no correlation between serum cholesterol and blood sugar levels in data from the Tecumseh population.[15] With regard to triglycerides, the data in the literature are not consistent. Most data, including those of Albrink, indicate only a modest association between hyperglycemia and hypertriglyceridemia as reviewed elsewhere.[16] In a small sample of 74 persons in Tecumseh, there was a tendency for persons with a high level of one to also have a high level of the other.[17] In the Pensacola 1000 aviator study,[18] there was likewise an association between triglyceride levels and glucose tolerance. One might have anticipated that patients with marked degrees of carbohydrate-sensitive hypertriglyceridemia would show reduced glucose tolerance,[16] but this was not so either in Ahrens' original series[19] or in the subsequent data by Kuo and Bassett.[20]

Weight Factor

The data from Tecumseh show no association between relative weight and glucose tolerance.[15] The actual relationship might be with weight *gain* rather than weight itself. Whatever the true connection between hyperglycemia and overweight, the association does not appear to be strong, notwithstanding the fact that weight reduction improves glucose tolerance. One tends to think of elevated blood sugar, triglycerides and weight as a triad, but Bierman[21] believes that these three abnormalities are basically different conditions which, being quite common, frequently happen to co-exist. Obesity, moreover, may not be a single entity. For instance, in the Tecumseh data, Evans and Ostrander[22] found that the sum of the subscapular and triceps skinfolds did not correlate with triglycerides; but their ratio, which is a measure of peripheral as opposed to central obesity, did so very significantly. Glucose tolerance correlated with neither skinfolds nor their ratio.

Multiple Variables

In these complex metabolic interrelationships, it may be a mistake to look only at two variables at a time. There may be a clustering of these abnormalities in some people but not in others, and such clustering may be masked in bivariant* analyses. We should search for syndromes of metabolic patterns of common disorders in the general population which, after all, generates the multitude of persons who develop coronary heart disease.

There is no evidence from the Tecumseh Study data that glucose tolerance correlates with other risk factors such as smoking[23] or physical inactivity.[24] Thus, if glucose tolerance is a risk factor toward coronary disease, it is likely to be a risk factor in its own right, although its association with high blood pressure may mediate part of this effect. There is a great need to find out more about the interrelationships between glucose tolerance, triglycerides and the lipoprotein pattern characterized in its fully expressed form by Fredrickson's type IV. Such data will be an essential part of determining the role of glucose tolerance and triglyceride levels as a risk factor.

---

*See Test Your Word Score Page 1213.

Atherogenesis*

Assuming the existence of a causal relationship between hyperglycemia and coronary heart disease, what are the possible mechanisms of atherogenesis? What facet of glucose intolerance might increase thrombotic tendency or myocardial susceptibility to infarction in a heart with an already marginal blood supply?[16]

Insulin Excess

The few animal experiments reported provide little help,[16] since alloxan-induced diabetes protects against atherosclerosis in rabbits, while, contrariwise, insulin prevents regression of atheromata in cockerels and also depresses lipase activity in aortas of alloxan-diabetic rats. That elevated insulin levels may be detrimental is suggested by a few studies in which immunoreactive insulin was shown to be elevated in patients with coronary disease, most recently by Tzagournis and coworkers.[6] and in at least three similar, limited studies previously reviewed.[16] It seems that insulin is involved specifically, because insulin-like activity was not found to be elevated in persons with coronary heart disease in the Tecumseh study.[17] According to Vallance-Owen,[25] on the other hand, the factor involved is the insulin antagonist which he has described. Delayed but enhanced insulin output is, of course, part of the abnormal response to a glucose load. It is true that in early or latent diabetes the output of insulin per unit of blood-sugar rise is less than normal. However, the total, as opposed to the relative, release of insulin is higher than normal. This absolute rather than relative insulin level is, perhaps, the signal which determines the effect of insulin on arterial lipids.[16]

Insulin Deficit

On the basis of the data just cited, it is plausible that coronary disease and hyperglycemia are linked because the metabolic defect manifested as hyperglycemia is accompanied by hyperinsulinemia which enhances atheroma formation. It seems hard to reconcile this attractive hypothesis with the equally attractive view of Kendall, in a recent editorial in *Circulation,* that the fault lies with insulin lack rather than insulin excess.[26] He recalls that the arterial intima is essentially avascular and hypoxic and that the integrity of the arterial cells depends on the energy supplied through anaerobic glycolysis. Insulin lack prevents glucose utilization as a source of energy and leads to arterial damage. This damage, which would be the initial pathological change, makes the artery susceptible to lipid infiltration. Insulin lack over large parts of the day may result from our habit of taking infrequent meals high in fat and low in slowly absorbed complex carbohydrates. By contrast, a constant supply of blood glucose, maintained by frequently ingested and slowly released complex carbohydrates, would assure a constant, adequate level of insulin. Large, widely-spaced meals high in simple carbohydrates cause both an irregular supply of insulin and a dissociation in the absorption of carbohydrate and fat.

When fat absorption is rising, carbohydrate absorption and insulin release are past their peak, and adipose tissue cells are filled with fat newly synthesized from the glucose just absorbed so that more of the absorbed fat is channelled to the liver to be converted into more lipoprotein which is then deposited in an artery already damaged through insulin lack. Thus, according to Kendall, the vicious circle closes. This theory and the hyperinsulinemia hypothesis are not necessarily mutually exclusive. If low levels of insulin are detrimental to the integrity of arterial cells, excessively high levels may be equally harmful, on account of the lipogenic action of insulin. It may be anticipated that there will be alternative or additional mechanisms proposed to explain the coexistence of hyperglycemia and coronary disease.

Treatment of Abnormal Glucose Tolerance

Is it desirable to treat people who have abnormal but not diabetic glucose tolerance tests? The answer to this question is now known. Drugs which act by releasing insulin may or may not be desirable. Although weight reduction frequently normalizes glucose tolerance, it is unknown what amounts, proportions and kinds of fat and carbohydrate in the diet are most apt to convert an abnormal curve to normal. Frequency of meals may also be a factor. On the basis of the tenuous hypothesis proposed, the criterion of a good dietary regime would not be primarily the normalization of the glucose tolerance test but the achievement of diurnally optimal insulin levels.

---

*See Test Your Word Score Page 1213.

Conclusions

There is clearly much room for research. What action should be taken, on the basis of current knowledge, if a person has a marginal abnormality in glucose tolerance? If the finding is clearly isolated, probably nothing; if associated with hypertension or obesity, both should treated; if associated with elevated serum lipids, first attention should be directed toward the lipids. In some instances, these measures will unaccountably rectify hyperglycemia. In others, the physician will have to stand by and practice the difficult art of *masterly* inactivity, which is quite different from *plain* inactivity. The answer whether or not to treat borderline hyperglycemia by diet or hypoglycemic drugs must come from clinical trials, which are now beginning to be instituted. In the meantime, there is a good case for believing that diminished glucose tolerance increases the risk of coronary heart disease and that the mechanism involved holds a major clue to the basic etiology of atherosclerosis.

A few people die young at 95 or 100. But a larger number become senile wrecks at 21. The growing cult of prolonging life, no matter how parasitic or obstructionist, is terrifying. Too many people are boasting about "hitting 70" or "hitting 80" who never hit anything else in their life, except perhaps a golf ball or a bottle.—Simeon Stylites

When it's more than a bad cold

your patient can feel better while he's getting better

Achrocidin®

Tetracycline HCl—Antihistamine—Analgesic Compound

Each tablet contains: ACHROMYCIN® Tetracycline HCl 125 mg.; Phenacetin 120 mg.;
Caffeine 30 mg.; Salicylamide 150 mg.; Chlorothen citrate 25 mg.

In tetracycline-sensitive bacterial infection complicating respiratory allergy, ACHROCIDIN brings the treatment together in a single prescription—prompt relief of headache and congestion together with effective control of the organisms frequently responsible for complications leading to prolonged disability in the susceptible patient.

For children and elderly patients you may prefer caffeine-free ACHROCIDIN Syrup. Each 5 cc contains: ACHROMYCIN (Tetracycline) equivalent to Tetracycline HCl 125 mg.; Phenacetin 120 mg.; Salicylamide 150 mg.; Ascorbic Acid (C) 25 mg.; Pyrilamine Maleate 15 mg.

Contraindications: Hypersensitivity to any component.

Warning: In renal impairment, since liver toxicity is possible, lower doses are indicated; during prolonged therapy consider serum level determinations. Photodynamic reaction to sunlight may occur in hypersensitive persons. Photosensitive individuals should avoid exposure; discontinue treatment if skin discomfort occurs.

Precautions: Drowsiness, anorexia, slight gastric distress can occur. In excessive drowsiness, consider longer dosage intervals. Persons on full dosage should not operate vehicles. Nonsusceptible organisms may overgrow; treat superinfection appropriately. Treat beta-hemolytic streptococcal infections at least 10 days to help prevent rheumatic fever or acute glomerulonephritis. Tetracycline may form a stable calcium complex in bone-forming tissue and may cause dental staining during tooth development (last half of pregnancy, neonatal period, infancy, early childhood).

Adverse Reactions: *Gastrointestinal*—anorexia, nausea, vomiting, diarrhea, stomatitis, glossitis, enterocolitis, pruritus ani. *Skin*—maculopapular and erythematous rashes; exfoliative dermatitis; photosensitivity; onycholysis, nail discoloration. *Kidney*—dose-related rise in BUN. *Hypersensitivity* reactions—urticaria, angioneurotic edema, anaphylaxis. *Intracranial*—bulging fontanels in young infants. *Teeth*—yellow-brown staining; enamel hypoplasia. *Blood*—anemia, thrombocytopenic purpura, neutropenia, eosinophilia. *Liver*—cholestasis at high dosage.

Upon adverse reaction, stop medication and treat appropriately.

Our travel-pak for summer cold and allergy sufferers.

Novahistine LP can speed your patients on their way, by providing prompt and continuous relief from the symptoms of summer colds and allergies. These continuous-release tablets contain a vasoconstrictor-antihistamine formulation that goes to work rapidly and lasts for hours. Even when nasal congestion is caused by repeated allergic episodes, the convenient twice-a-day dosage of Novahistine LP makes it easy for most patients to enjoy relief all day and all night. When symptoms are severe, a third dose of one or two tablets may be safely given. Use with caution in patients with severe hypertension, diabetes mellitus, hyperthyroidism or urinary retention. Caution ambulatory patients that drowsiness may result.

Obesity and Nutrition Education

Community Approach to Prevention of Coronary Heart Disease*

GEORGE CHRISTAKIS, M.D.†
New York, New York

THE PREVENTION and treatment of obesity as an effective deterrent to the development of coronary heart disease is one of the greatest challenges facing medicine today. No condition, as Dr. Van Itallie observed, is easier to diagnose and more difficult to treat; for the road to weight reduction, as evidenced by the medical literature, is paved with the good intentions of nutritionists and physicians recommending regimens from anorexigenic‡ agents to starvation, and multitudes of reducing diets of various proportions of carbohydrates, fats and proteins. The long-term success of weight reduction regimens remains pitiable.

Indeed obesity *is* a complex problem, a large and elusive shadow, that has followed man throughout the course of history. It is deeply interwoven with his psychic nature and with his culture and environment, and it is now one of the major health problems of western civilization.

Results and Obesity Clinics

Bureau of Nutrition

Community approaches to weight reduction have been relatively few and unsuccessful. The Bureau of Nutrition Obesity Clinic regimen included a 1200-calorie reducing diet. Our review of 2,045 obese subjects treated in these clinics revealed that approximately 26 per cent attained normal weight or within 10 per cent of normal weight, using Metropolitan Life tables as criteria of "normalcy." Seventy-four per cent failed to achieve this.

These results would appear singularly disappointing were it not for the fact that those who failed to attain our strict criteria of normal weight did lose, nevertheless, a considerable amount of weight. However, the complex and tragic aspect of obesity is again in evidence when one considers the percentage of weight loss that is regained.

Mt. Sinai Hospital Nutrition Clinic

Since January of this year, we have initiated a new weight-reduction program in the Nutrition Clinic of the Mount Sinai Hospital. The screening of obese patients is carefully accomplished by detailed physical examinations: anthropometric measurements of body composition, and laboratory detaminations including a hemogram, serum cholesterol, triglyceride, lipoprotein electrophoresis, phospholipids, and a serum vitamin profile of vitamins A, beta carotene, C and B_{12}. Efforts in small group sessions with experienced nutritionists, using attractive audiovisual techniques, do not appear to be meeting with any greater success than the Bureau of Nutrition program.

Anti-Coronary Club Project

However, the results of the Anti-Coronary Club Study Project now in its eleventh year are most encouraging. The objectives of the Club are the reversal of the risk factors of hypercholesterolemia and obesity.

Detailed dietary history analyses were made of 570 Anti-Coronary Club subjects by age and weight status before they were given a serum-cholesterol lowering diet.

Results of Serum-Cholesterol Lowering Diet

Calorie Intake

In every age group, the excess caloric intake of the overweight men was approximately 200 calories per day compared to the normal-weight men. This relatively moderate excess of calories in the face of the decreasing caloric requirement of advancing age, plus the accompanying sedentariness of urban life very likely play important roles in the pathogenesis of obesity.

Consumption of Fat

Regardless of weight, the subjects consumed less fat with increase in age. In all age groups studied, the obese men ate more fat than normal weight men, though the percentage of fat derived from saturated, monounsaturated and polyunsaturated sources remained quite constant. This is reflected in the similarity of the polyunsaturated to saturated fatty acid ratios in the adipose tissues of both the normal-weight and the obese subjects. This finding resulted from fatty acid composition studies of subcutaneous adipose tissue aspirated from normal weight and obese subjects.

Prevalence of Hypertension

The relative prevalence of hypertension (over 95 mm diastolic) and hypercholesterolemia (over 260 mg%) is given in Table 1.

Incidence of Coronary Events

The Prudent Reducing Diet is summarized in Tables 2 and 3. In Table 1 the effects of the "Regular Prudent Diet" (for normal-weight men) and the Prudent Reducing Diet are seen in reversing obesity, hypercholesterolemia and hypertension. The Anti-Coronary Club data collated as of November 30, 1967, are given in Table 4. We observed 17 confirmed new coronary events in 941 experimen-

TABLE I

Percent of Risk Factors Among 332 Experimental and 329 Control Subjects at Time of Entry and After 2 and 4 Years of Observation

	Experimental			Control

‡Diastolic pressure of 95 mm Hg or more.

tal subjects totaling 3,954 man-years of experience vs. 32 events among 457 control subjects totaling 3,122 man-years of experience. Per 100,000 man-years of experience, the incidence rate of new events for the experimental group is 430 vs. 1,025 for the controls.

Concluding Comments

A two-year study was conducted to identify sociological and psychological attributes of subjects remaining in the study and those who dropped out. By analysis of 370 interviews with persons from both groups, specific behavioral patterns were delineated. Those who dropped out of the study were more closely identified with a 'parochial' orientation. They belonged to a closed, shared and traditional social system. By contrast, members of the study who remained active showed traits of a 'cosmopolitan' orientation. They were open, individual, and progressive. Such information will be useful if methods developed by the Anti-Coronary Club are incorporated into public health programs for the prevention of coronary heart disease.

The unusual degree of success in reducing the weight of obese subjects in this Club, followed by maintenance of normal weight, may be attributable both to the unusual composition of the group and to the intense nutritional guidance given the subjects by the study's public health nutritionists. Subjects are seen at least every six weeks upon entry to the study. During the active phase of weight reduction,

‡ Experience accumulated while attending study facilities annually or with successful regular contact by mail or phone since active attendance at panel or nutritionist sessions were discontinued. No professional supervision in this phase.

they are seen every week. Despite the concentration of personnel and effort in lowering serum cholesterol and reduction of weight, the results obtained utilizing the techniques of the Anti-Coronary Club study project can be the basis of preventive community medical programs to combat coronary heart disease. For high-risk screening, the practicing physician can utilize the serum cholesterol and triglyceride determinations. He can readily practice preventive medicine in his own office in an effort to reverse the risk factors affecting his patients.

The decrease in morbidity rate in the experimental group could not be ascribed to any change in cigarette-smoking habits; the Anti-Coronary Club Study protocol was limited to diet modification. It is recognized, however, that efforts to reduce other risk factors such as psychic stress and lack of physical activity could contribute further avenues to coronary heart disease control.

The American Medical Association has recognized the importance of controlling the level of serum cholesterol in high-risk groups and has suggested the need to control high serum-cholesterol levels observed in the young adult. The American Heart Association has repeatedly emphasized the preventive role of serum cholesterol-lowering diets and has recently indicated that appropriate dietary changes should be instituted for the public in general. The results described appear to be confirmed by other prospective diet-heart studies in progress, specifically by those of Leren, Turpenin and Birenbaum. There is, therefore, good reason to expect progress in reducing a paramount public health problem by implementing the knowledge at hand.

Chronic Condition

Let's diagnose the patient who
Gets pains when doctors' bills are due,
Excruciating pains that stab
His shoulder when he starts to grab
Some cash from out his pocketbook.
Oh, doctor, what an anguished look,
And what a throbbing of the neck
If he should try to write a check.
It shows that there's congestion, tightening,
A state of shock that's truly frightening.

If such a sickness needs a name
To give it proper place and fame,
Here's one (if you've a better, write us);
Disbursitis.

—Richard Armour: The Medical Muse, 1963.

Keeping Up To Date

A doctor picking up his car at a garage was highly indignant at the size of the repair bill. "All this for a few hours' work?" he protested. "Why, you charge more for your work than we of the medical profession do!"

"Well now," replied the mechanic, "that's just how it should be. You doctors have been working on the same old model since time began, but we've got to learn a brand-new model every year."*

The Cardiovascular Risk

Associated with Different Levels and Types of Elevated Blood Pressure*

ALBERT OBERMAN, M.D.†
Birmingham, Alabama

WILLIAM R. HARLAN, M.D.‡
Richmond, Virginia

MARGARET SMITH, Ph.D.§
ASHTON GRAYBIEL, M.D.¶
Pensacola, Florida

THE ASSOCIATION BETWEEN elevated blood pressure found in over 17 million of our population and atherosclerotic cardiovascular disease has been thoroughly documented in the clinical situation, experimental laboratory and population studies.

Risk from Elevated Blood Pressure

The risk gradients from elevated blood pressure are reflected in the report[1] by the Society of Actuaries (Table 1). Mortality ratios increase sharply for both systolic and diastolic blood pressure. As the systolic pressure increases for any given diastolic pressure, the risk also increases, approaching two-and-a-half times—even when moderate blood pressures are considered. The same relationship holds for diastolic. The highest mortality ratio of two-and-a-half to three times is at the highest systolic-diastolic combination. Thus, either systolic or diastolic pressure is a measure of risk.

Risk from Selected Causes

Figure 1 shows the increased risk for the general categories: heart and circulatory diseases against vascular lesions of the central nervous system for different levels of blood pressure. When the systolic or diastolic blood pressure is slightly elevated, the risk is about one-and-a-half times; if both are elevated the risk jumps to about two-and-a-half times, further rising to three and six times at higher levels (though not marked elevations) for cardiovascular disease and strokes.

Hypertension vs. Normotension

The risk ratios are obviously dependent on

"end points," but as indicated previously these "minor" blood pressure elevations, so-called "borderline" or "high normals," both systolic and diastolic, are not innocuous.

The incidence data from longitudinal studies[2-6] are helpful. We have selected several from which data for both coronary heart disease and stroke are available (Figure 2). The incidence rate for hypertensives (BP ≥ 160/95) versus normotensives (BP < 140/90) is about two-and-a-half times that for coronary heart disease and five times that for thrombotic stroke in the Framingham Study; in the Los Angeles Study one-and-a-half and five times; and in the Chicago Study, considering only diastolic, three and four times.

Yet we know that elevated blood pressure alone may not increase the risk for coronary heart disease. For example, the Japanese have a high incidence of stroke associated with their high prevalence of hypertension, but they experience no excess of coronary heart disease.

Coronary heart disease is of multifactorial etiology; the risk of elevated blood pressure is potentiated by other factors such as high blood cholesterol level and heavy smoking. Individuals with high levels of these factors exhibit four to six times greater risk than those low in all three.[7] In fact, two thirds to three fourths of all men sustaining coronaries have cholesterol, high blood pressure, or both.[7,8]

The relationship between elevated blood pressure level and cardiovascular risk is by no means simple. Some people may live for years with an elevated blood pressure but with no overt manifestations. Others after a short period of elevated blood pressure develop marked physiologic changes.

What then are the relationships between patterns of blood pressure and alteration of target organs upon which the prognosis depends?

Is the increment or trend of blood pressure with age more important than a current reading? Stamler[9] has shown that diastolic blood pressure does not necessarily increase with age; Miall and co-workers[10] demonstrated that neither systolic nor diastolic pressure necessarily increases with age, but that those individuals with the highest blood pressure show the greatest increments.

Fig. 2—Blood Pressure Level and Risk Ratios for Cardiovascular Disease in Men. Calculated From Incidence Data.

Weight and Parental Longevity

Figure 3 demonstrates that the blood pressure of a group of young men in their mid-twenties is related, in part, to parental longevity but not to obesity.[11] However, as the group progressed through middle age, weight gain became increasingly important and interacted with parental longevity. This is depicted in the Table by the increased height in the first two columns when the men were in their 20s, and then the separation of the first and third columns representing weight gain as the men grew older. The column with both weight gain and short-lived parents demonstrates that men with both these characteristics definitely had the highest systolic blood pressure in later life. These findings were substantiated statistically by an analysis of variance and an estimation of the components of variance.

In general, obesity and other risk factors potentiate each other, and it is not unreasonable to presume that subjects with parental history of early death or vascular disease may be more vulnerable to blood pressure elevations, suggesting that familial and environmental factors do increase target organ susceptibility.

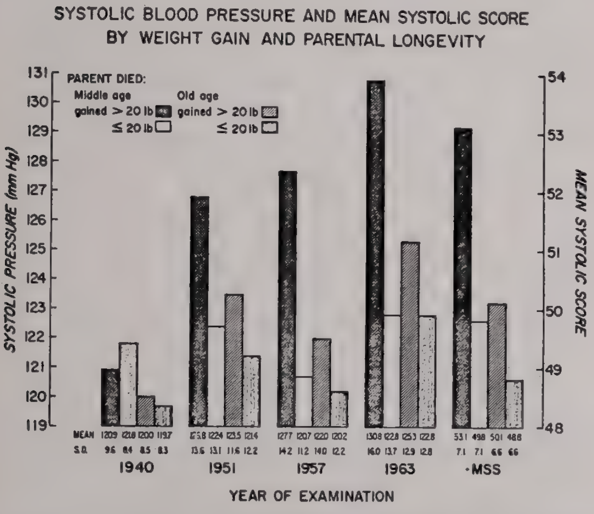

Fig. 3.—Systolic Blood Pressure and Mean Systolic Score by Weight Gain and Parental Longevity.
Source: Thousand Aviator Study.[11]

Patterns of Blood Pressure

Dustin[12] and Thurm[13] independently found that hypertensives who were able to reset their baro-receptors or remain normotensive after discontinuance of drug therapy had two factors in common, namely, mild hypertension before the onset of treatment and few cardiovascular complications.

Patterns of blood pressure other than increment may be important. Concerning blood pressure variability versus the average level, Pollack and colleagues[14] concluded that average blood pressures properly characterized the individual's blood pressure for risk appraisal. However, McKensie and Sheppard[15] felt that there was a distinctive effect of a previously elevated systolic pressure. Levy and others,[16] in a study of over 22,000 U. S. Army officers, found that men with transient elevations of blood pressure have as much as three to four times higher retirement rates and two to three times higher cardiovascular-renal mortality rates than the officers without this supposedly minor finding. A long-term study[17] also revealed that the increase in risk from coronary artery disease and cerebrovascular disease was higher for people with frequently elevated blood pressure and higher still for those with consistently elevated pressures for those of all ages. Sokolow and colleagues,[18] in a short-term study over several days with multiple measurements using a portable blood pressure apparatus, found that blood pressure variability did not relate to development of hypertensive complications which were mainly determined by the average level of arterial blood pressure. Thus, there is no simple answer to this question, in part because of the difficulties in determining blood pressure variability.

Threshold of Damage

Is there a critical point or threshold of blood pressure that damages different end organs, or is the relationship continuous for all? Also, are the associations with systolic blood pressure the same as those with diastolic?

In an attempt to identify some of the factors and interactions involved in the damage to target organs, we will report on data collected at four points in time on a cohort of initially normotensive men followed for 24 years.[19] We sought to relate trends and variability of blood pressure from early adulthood to middle age with target organ damage as manifest by heart size, electrocardiogram measurements, and pertinent laboratory measures. At the most recent examination the men were 47 years old. Systolic and diastolic blood pressures at ages 24, 35, 41, and 47 and blood pressure changes between these ages were related to other variables. We evaluated the effect of blood pressure on the basis of mean blood pressures over the entire period of study; a mean score representing overall rank in the cohort for the blood pressure evaluations; and a classification based on mean blood pressure at or above arbitrary levels (140 or 90) during any of the four examinations. Finally, we also used a measure of cardiac work, the systolic tension time. We analyzed the interactions and contributions of the various blood pressures through multiple correlations using the cardiovascular measurements as criterion variables and blood pressure plus a number of related measurements such as weight gain, skin-folds, smoking, and parental longevity as predictors (Table 2). In other words, we tried to predict things like heart rate at age 47 from previous parameters such as blood pressure change from age 24 to 47, weight change, lipids, etc. To be selected, each predictor must contribute something unique, e.g., if two blood pressures are correlated with the criteria only the one with the higher relationship would be selected. The other predictor would be selected only if it added something unique to prediction of the criterion variable.

Measurements Used for Criterion and Predictor Variables in Multiple Correlations.

Multiple Correlations

Heart rate, fundus abnormalities, heart size, Sf 20-400 lipoproteins, two-hour post-prandial glucose, vital capacity and electrocardiogram measures of amplitude and frontal vectors at age 47 were a function of blood pressure and were independent of weight. Some variables such as fundus, heart size, vital capacity, 20-400 lipoprotein and ratio T/R in lead I related to blood pressure measurements taken as early as age 35. Other associations were not apparent until age 41 or 47.

Cumulative Multiple Correlations

Generally, blood pressure increments, mean blood pressures and measures of variability did not predict end organ change better than the most recent blood pressure, although for particular measurements they added unique information. For example, the highest diastolic pressure was the most important *blood pressure* predictor of frontal QRS Vector (Figure 4) although weight was the best predictor. Thus for predicting frontal QRS vector, body build and peak diastolic blood pressure were best. For the fundus (Figure 5) the variables chosen as predictors were the 1963 diastolic pressure and the alcohol intake; this

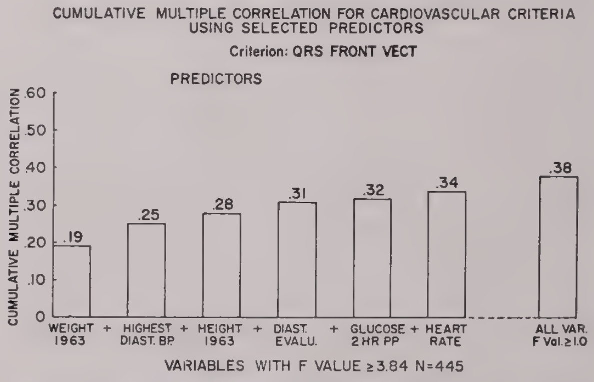

Fig. 4—Cumulative Multiple Correlation for Cardiovascular Criteria Using Selected Predictors. Criterion: QRS FRONT VECT

table illustrates that several patterns of blood pressure may have predictive value. For example, systolic blood pressure variability contributed something unaccounted for by the 1963 diastolic blood pressure, the best predictor. Parental longevity and cigarette smoking further added to the correlation. For the transverse diameter of the heart (Figure 6), though a number of variables are listed, only weight and mean diastolic blood pressure of those listed contributed substantially to the correlation coefficient. As expected (Figure 7), vital capacity related well to height and cigarette smoking, but also unexpectedly to a number of other measures, especially change in systolic blood pressure at age 24 to 47.

Stature and smoking both relate to the risk of coronary heart disease as well as to vital capacity. The fact that skinfold thickness and systolic blood pressure also act as predictors of vital capacity may indicate that the relationship noted between vital capacity and coronary heart disease may be mediated, at least in part, through these factors. In other words, vital capacity may be a risk factor only through its association with other factors and not through any inherent physiologic relationship. The commonly used electrocardiogram criteria for LVH ($SVI+RV_5$ or V_6) were independently related to the most recent systolic blood pressure, weight, cigarette smoking, and measures of blood pressure variability. It can be seen that various patterns of blood pressure may differ in importance in relating to criteria of end organ damage.

There is no marked discrepancy between systolic and diastolic blood pressures as predictors of other variables, but overall the diastolic pressures were better.

Furthermore, not all relationships were continuous (Figure 8). Putting all the variables in standard units it seems that those on the left differ primarily from those at the upper end of the blood pressure distribution; on the other hand, the ratio of the T wave to the R wave in Lead 1 differs primarily from those at the low end of the blood pressure distribution. The continuous relationships are apparent in the center of the slide. It may be that if we look at all end organs together the relationship is continuous, but for each individual parameter the association may be noncontinuous.

Concluding Summary

Development of atherosclerotic cardiovascular disease and subsequent mortality are obviously related to blood pressure levels. Target organ damage may be sustained at an early age with only moderate elevations of blood pressure. Recent studies[12,13] suggest that possible resetting of baro-receptors or other mechanisms after hypertensive therapy can be accomplished only if the therapy is started early and before cardiovascular complications. Blood pressure should be maintained at low levels preferably without a period of elevation of either systolic or diastolic. Not only should blood pressure be kept low, but attention given to concomitant variables such as diet, weight, smoking—alteration of which may potentiate the beneficial effects of reduction of blood pressure. Familial factors measured by parental longevity in our study, admittedly a gross index, did not materially aid our predictors; on the other hand, environmental factors, by virtue of influencing target organs, may be of critical importance in determining prognosis for hypertensives.

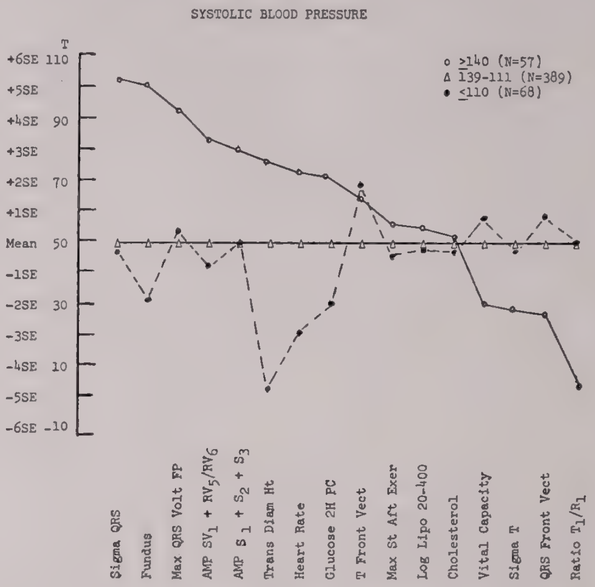

Fig. 8—T-Score Means of Trichotomized Blood Pressure Groups for Selected Variables. (T mean = 50, Std Dev = 10; T = $\frac{10}{SE_m}$ (M-μ) + 50; SE$_m$ = $\frac{\sigma}{\sqrt{N}}$)

Out of a hundred diseases, fifty are caused by our own faults and forty by our carelessness.—Paolo Mantegazza

Gross Obesity*

The Cardiovascular Consequences

JAMES K. ALEXANDER, M.D.†
Houston, Texas

I would like to address myself to three questions: First, what are the circulatory effects of gross obesity? Second, how reversible are these effects once manifest? Third, what can be done to achieve weight reduction in very obese subjects? The last is the most difficult question and the one about which we know least.

Circulatory Effects of Gross Obesity

Gross obesity has easily demonstrable circulatory effects. It leads to an increase in the circulating blood volume, to an increase in the cardiac output and to an increase in blood pressure in a sizable percentage of such subjects. Because of the increase in the volume and pressure work load on the heart, the work of the heart is greater. Cardiac hypertrophy usually develops, and ultimately congestive heart failure may supervene.

Increased Blood Volume

Some data that we have collected in such subjects on blood volume are shown in Figure 1. As the amount of weight over ideal increases, the circulating blood volume tends to

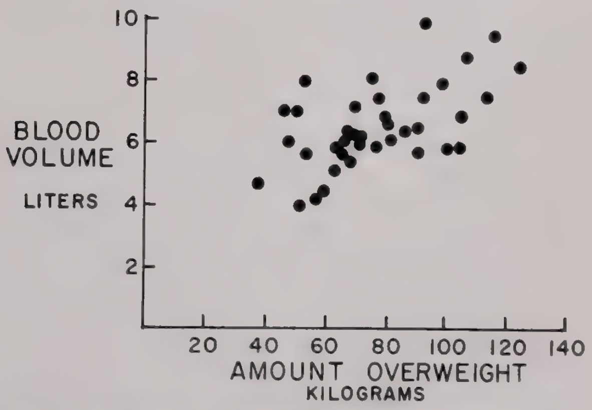

Fig. 1—Relationship between blood volume and amount of excess body weight in 40 very obese subjects.

---

*These studies have been supported by U. S. Public Health Service Grants HE-3006 and HE-5435, and the Houston Heart Association.

Presented at the Minnesota Symposium on Prevention in Cardiology, May 2-3, 1968 in Rochester, Minnesota.

†Professor, Baylor University College of Medicine, Department of Internal Medicine, Texas Medical Center.

rise, and when there is a gain of 200 pounds, the blood volume is about double the normal.

High Cardiac Output

Figure 2 shows what happens to the amount of blood that the heart must pump under these circumstances. There tends to be a correlation between the cardiac output and the increase in body weight. If you are 200 pounds overweight, at rest your heart pumps about twice what the heart of the subject at ideal weight would have to pump.

Elevation of Blood Pressure

In about two thirds of these subjects blood pressure is elevated; however, in the remainder blood pressure is normal. Hence we may conclude that, while obesity does predispose to hypertension, the fact that an individual is grossly overweight does not necessarily mean that he is also hypertensive. These data are based on direct intra-arterial pressure measurements. If the amount of blood that the heart pumps per unit time increases and if the pressure under which the blood must be delivered to the systemic circulation is elevated, the work of the heart is increased.

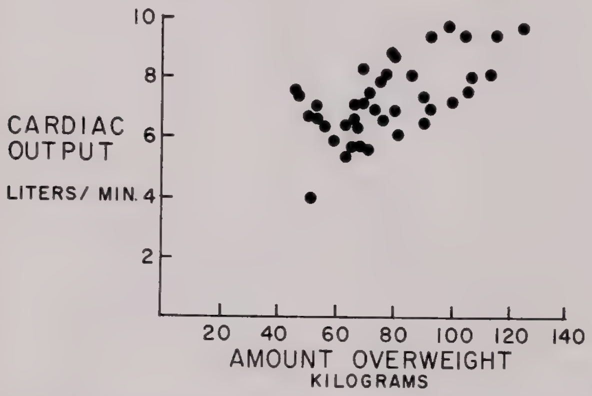

Fig. 2—Relationship between cardiac output and amount of excess body weight in 40 very obese subjects.

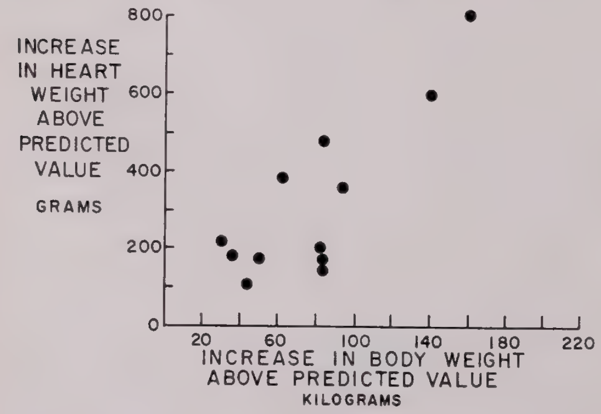

Fig. 3—Relationship between increment in heart weight and body weight above predicted values in 12 very obese subjects.

Enlarged Heart

These patients tend to have large hearts. Figure 3 shows the results of a study that we did some years ago. The hearts of a selected group of such very obese subjects were examined at autopsy. The heart weight tends to be increased as the body weight increases. This roughly linear relationship must tend to plateau, because since then we have carried out an autopsy on a 700-pound man and his heart weight was something of the order of 400 to 500 grams over the predicted level. Figure 4 shows the heart of a patient six feet tall, weighing 500 pounds at death. The tremendous hypertrophy of the left ventricle, the ventricular septum, and the right ventricle can all be seen. The left ventricle is about twice normal thickness. The total heart weight was 1100 grams, about 800 grams over the predicted weight. The increase in weight is clearly the result of myocardial hypertrophy and not an increase in epicardial fat or fatty infiltration of the myocardium.

Congestive Heart Failure

More recently we have surveyed 3,500 consecutive autopsies in the Veterans Administration Hospital in Houston, where we found nine patients 300 pounds in weight or over at the time of death, all of whom had gross and microscopic evidence of congestive failure: that is, systemic and pulmonary congestion. All had cardiac hypertrophy involving the left ventricle and in two cases involving the right ventricle. Six of these patients had clinical manifestations of cardiac failure prior to death; hence in very obese subjects, cardiac failure is frequent and plays a significant role in the demise of the patient.

Reversibility

In nine subjects we have been able to achieve weight loss varying from 85 to 185 pounds over periods of observation varying from four to 36 months. In all three instances where the pressure was elevated it did tend to fall to or toward normal following weight reduction. In those in whom the blood presure levels tended to be normal, there was a small reduction. Blood volume and cardiac output fell toward normal in every instance.

However, our data suggest that over the period of several months to three years that we observe these patients there was no tendency to regression of hypertrophy; there is little change in the filling pressure of the left ventricle, and it rose on exercise just as much as it did before weight reduction. Therefore we have no evidence to indicate that diminished myocardial compliance or ventricular hypertrophy regress with weight reduction.

Weight Reduction

In order to achieve weight reduction in these very obese subjects we found it necessary to hospitalize them under direct observation for periods of several weeks or months. Among well over 100 patients in an eight-year period, in only a few instances has significant weight reduction been achieved on an out-patient basis. We have had no success whatsoever using appetite-depressant drugs. If the patient is motivated to lose weight, he will do it irrespective of drugs. Within a year after discharge from the hospital, a patient with reduced weight will frequently return at control weight. In these very obese patients the approach to weight reduction is difficult and often discouraging. These patients commonly have a genetic or familial predisposition. Perhaps a coordinated approach by the internist, the psychiatrist, the dietitian, the social worker, and a variety of para-medical personnel brought to bear in a community effort may be more productive. It is necessary to change the entire way of life.

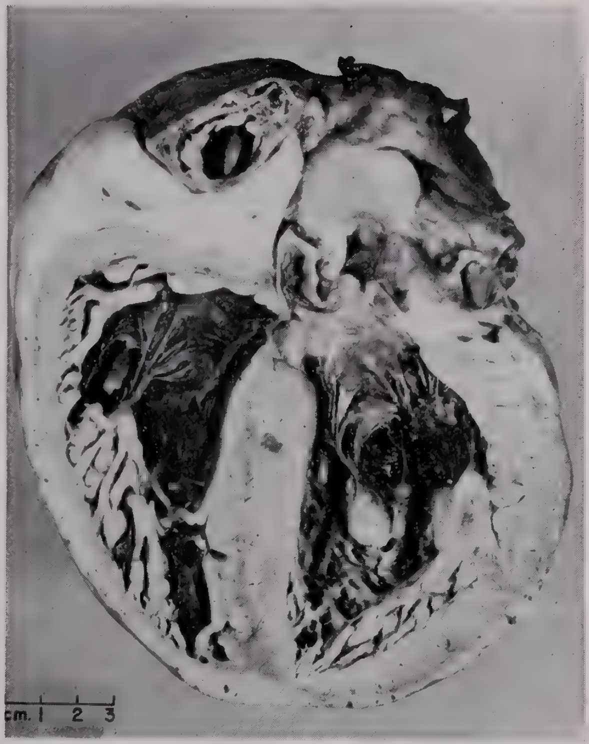

Fig. 4—An example of marked ventricular hypertrophy in an extremely obese patient with a body weight of 497 pounds. The heart weight is 1100 grams. There is gross increase in the thickness of both ventricular walls, particularly the left. Note that epicardial fat is not especially increased.

Conclusions

Management of obesity presents a great challenge. Perhaps those of us who are interested can best perform our function by educating the physician and the public to the consequences of obesity, so that obese individuals will be better motivated to lose weight. Prevention certainly cannot be overemphasized. Our immediate goal is to make the physician and the patient conscious of the problem.

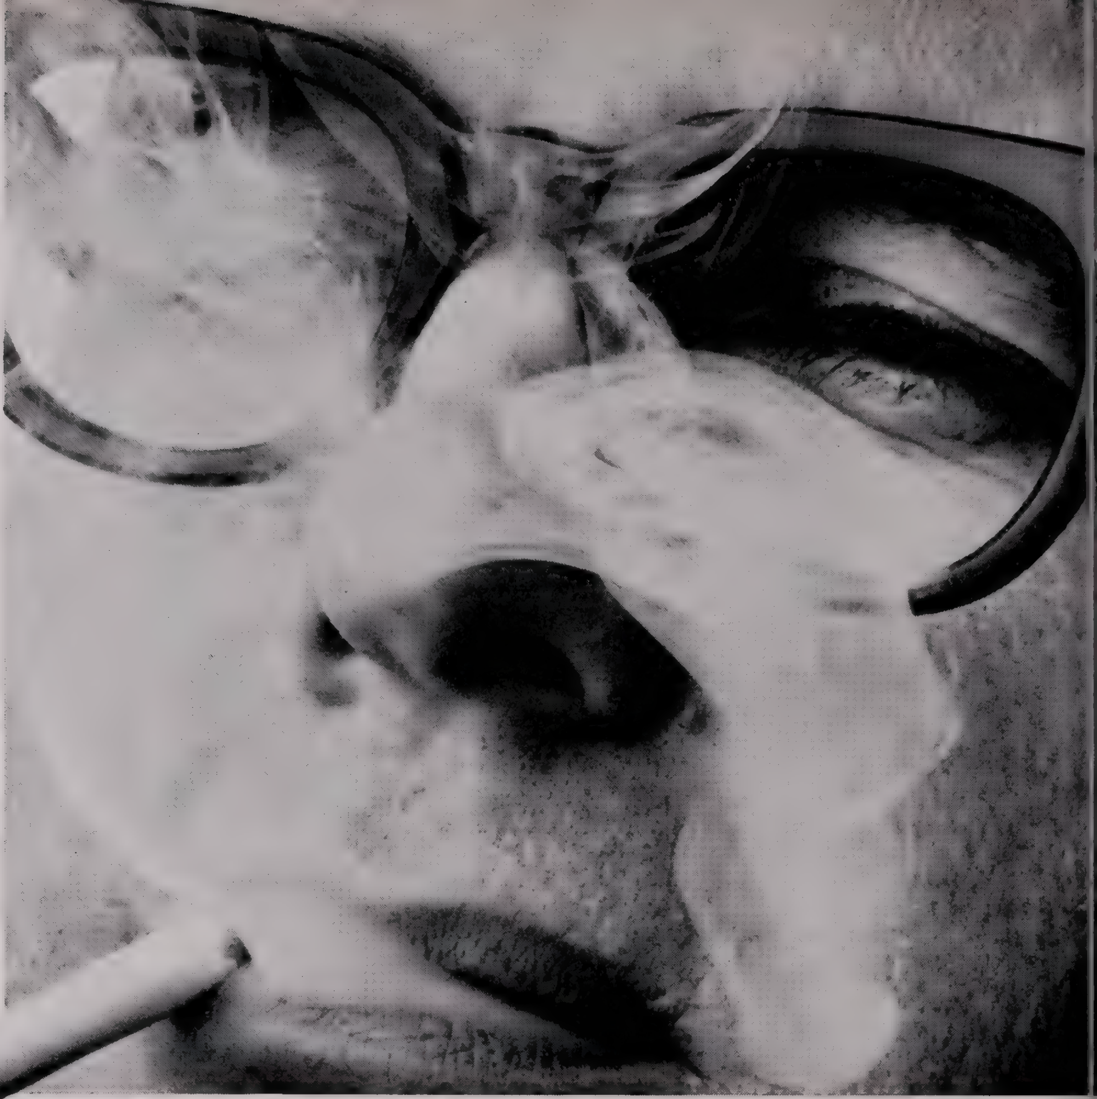
Overweight

Many a middle-aged woman is thick and tired of it.



Clues to PVD

The heavy smoker with vasospasm

He may be comparatively young or approaching middle age. Typically, he is a heavy cigarette smoker—a pack or more a day for a number of years. Whether smoking is a causative or an important exacerbating factor in peripheral vascular disease is still under discussion. But the vasoconstrictive effects of nicotine are firmly supported by a substantial body of laboratory and clinical evidence, and the close association is now generally accepted.

Thus, a history of heavy smoking coupled with vasospasm may serve as warning signals to the physician. When a diagnosis is established, therapeutic measures are directed toward increasing the local circulation, and appropriate management of the patient's general medical needs should be instituted. These include the important safeguards of keeping warm and refraining from smoking.

Before prescribing Roniacol Timespan (nicotinyl alcohol tartrate), please consult complete product information, a summary of which follows.

Indications: Conditions associated with deficient circulation; *e.g.*, peripheral vascular disease, vascular spasm, varicose ulcers, decubital ulcers, chilblains, Meniere's syndrome and vertigo.

Caution: Roche Laboratories endorses caution in the administration of any therapeutic agent to pregnant patients.

Side Effects: Transient flushing, gastric disturbances, minor skin rashes and allergies may occur in some patients, seldom requiring discontinuation of the drug.

Dosage: 1 or 2 Timespan Tablets morning and night.

How Supplied: Timespan Tablets—150 mg nicotinyl alcohol in the form of the tartrate salt —bottles of 50.

Important in total management of peripheral vascular disease, vascular spasm or chilblains

Roniacol® Timespan®

(nicotinyl alcohol tartrate)

for relief of ischemic symptoms

Convenience of b.i.d. dosage—sustained-release Timespan Tablets usually provide prolonged relief of ischemic symptoms with two doses daily.

Smoothness of onset—the action of Roniacol (nicotinyl alcohol) is smooth and gradual in onset, rarely causing severe flushing.

Selectivity of action—relaxes the musculature of peripheral blood vessels.

High degree of safety—side effects seldom require discontinuation of therapy.

Mild ulcerative colitis may be triggered here...

In mild ulcerative colitis, a number of factors can precipitate an attack: for instance, dietary indiscretion, such as eating raw foods, or emotional overreaction, such as that aroused by financial difficulties. No matter what causes the patient's sensitive colon to "act up," he soon suffers from acute discomfort...and often, from anxiety and apprehension as well. Such patients frequently respond well to adjunctive dual-action Librax® therapy.

Librax combines, in a single convenient capsule, the well-known antianxiety effect of Librium® (chlordiazepoxide HCl) and the dependable anticholinergic/antispasmodic effect of Quarzan® (clidinium Br). Therefore, as Librax helps to relieve the patient's excessive anxiety and reduce his overreaction to stress, it also, at the same time, helps to control hypersecretion and hypermotility, thus relieving spasm and abdominal discomfort.

With Librax, the dosage schedule is simple: 1 or 2 capsules, t.i.d. or q.i.d., will in most cases bring the patient significant relief of both the emotional and physical elements that contribute to his psychovisceral disorder.

Before prescribing, please consult complete product information, a summary of which follows.

INDICATIONS: Indicated as adjunctive therapy to control emotional and somatic factors in gastrointestinal disorders.

CONTRAINDICATIONS: Patients with glaucoma; prostatic hypertrophy and benign bladder neck obstruction; known hypersensitivity to chlordiazepoxide HCl and/or clidinium bromide.

WARNINGS: Caution patients about possible combined effects with alcohol and other CNS depressants. As with all CNS-acting drugs, caution patients against hazardous occupations requiring complete mental alertness (*e.g.*, operating machinery, driving). Though physical and psychological dependence have rarely been reporte on recommended doses, use caution in administering Librium (chlordiazepoxide hydrochloride) to known addiction-prone individuals or those who might increase dosage; withdrawal symptoms (including convulsions), following discontinuation of the drug and similar to those seen with barbiturates, have been reported. Use of any drug in pregnancy, lactation, or in women of childbearing age requires that its potentia benefits be weighed against its possible hazards As with all anticholinergic drugs, an inhibiting effect on lactation may occur.

PRECAUTIONS: In elderly and debilitated limit dosage to smallest effective amount to preclude development of ataxia, oversedation or confusion (not more than two capsules per day initially; increase gradually as needed and toler-

or here.

ted). Though generally not recommended, if
ombination therapy with other psychotropics
eems indicated, carefully consider individual
harmacologic effects, particularly in use of po-
entiating drugs such as MAO inhibitors and
henothiazines. Observe usual precautions in
resence of impaired renal or hepatic function.
aradoxical reactions (*e.g.*, excitement, stimula-
ion and acute rage) have been reported in psy-
hiatric patients. Employ usual precautions in
reatment of anxiety states with evidence of im-
ending depression; suicidal tendencies may be
resent and protective measures necessary. Vari-
ble effects on blood coagulation have been
eported very rarely in patients receiving the
rug and oral anticoagulants; causal relation-
hip has not been established clinically.
ADVERSE REACTIONS: No side effects or
anifestations not seen with either compound
lone have been reported with Librax. When
hlordiazepoxide hydrochloride is used alone,
rowsiness, ataxia and confusion may occur,
specially in the elderly and debilitated. These
are reversible in most instances by proper dosage adjustment, but are also occasionally observed at the lower dosage ranges. In a few instances syncope has been reported. Also encountered are isolated instances of skin eruptions, edema, minor menstrual irregularities, nausea and constipation, extrapyramidal symptoms, increased and decreased libido—all infrequent and generally controlled with dosage reduction; changes in EEG patterns (low-voltage fast activity) may appear during and after treatment; blood dyscrasias (including agranulocytosis), jaundice and hepatic dysfunction have been reported occasionally with chlordiazepoxide hydrochloride, making periodic blood counts and liver-function tests advisable during protracted therapy. Adverse effects reported with Librax are typical of anticholinergic agents, *i.e.*, dryness of mouth, blurring of vision, urinary hesitancy and constipation. Constipation has occurred most often when Librax therapy is combined with other spasmolytics and/or low residue diet.

two good reasons for prescribing LIBRAX®

Each capsule contains 5 mg chlordiazepoxide HCl and 2.5 mg clidinium Br.

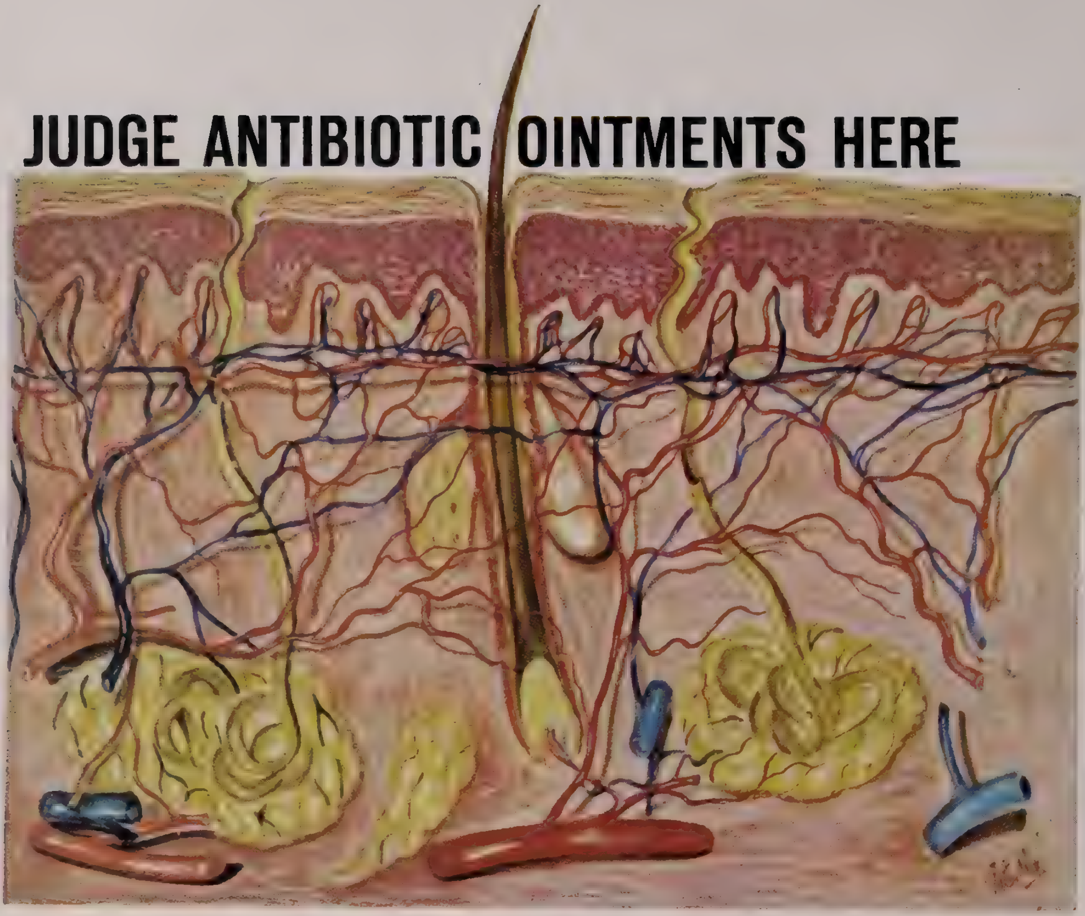
JUDGE ANTIBIOTIC OINTMENTS HERE



Results on skin are final proof of any topical antibiotic's effectiveness

No in vitro test can duplicate a clinical situation on living skin. 'Neosporin' (polymyxin B—bacitracin—neomycin) Ointment has consistently proven its effectiveness in thousands of cases of bacterial skin infection. The spectra of the three antibiotics overlap in such a way as to provide bactericidal action against most pathogenic bacteria likely to be found topically. Diffusion of the antibiotics from the special petrolatum base is rapid since they are insoluble in the petrolatum, but readily soluble in tissue fluids. The Ointment is bland and nonirritating.

Caution: As with other antibiotic preparations, prolonged use may result in overgrowth of nonsusceptible organisms and/or fungi. Appropriate measures should be taken if this occurs. Articles in the current medical literature indicate an increase in the prevalence of persons allergic to neomycin. The possibility of such a reaction should be borne in mind.

Contraindications: This product is contraindicated in those individuals who have shown hypersensitivity to any of its components.

Supplied: Tubes of 1 oz., ½ oz. with applicator tip, and ⅛ oz. with ophthalmic tip.

Veterans Multiclinic Trial of Drug Treatment in Hypertension[*]

MARK L. ARMSTRONG, M.D.[†]
Iowa City, Iowa
RUSSELL B. TEWKSBURY, Sc.D.[‡]
LAWRENCE W. SHAW[‡]
EDWARD D. FREIS, M.D.[§]
Washington, D. C.

The value of antihypertensive drug treatment in severe or malignant forms of hypertension has been widely accepted, but the value of drugs in mild and moderate hypertension has been disputed. There has been no question that agents are at hand which effectively lower blood pressure; but a more basic question has been posed: Is the reduction in blood pressure really beneficial; does it significantly prevent *morbidity* in patients with less than severe hypertension? It became apparent by 1963 that adequately controlled, prospective studies of sufficient sample size were needed to evaluate this question. The Veterans Administration Cooperative Study Group on Antihypertensive Agents therefore commenced an investigation of this type in early 1964 under the chairmanship of Dr. Edward Freis of Washington. Twelve Veterans Administration Hospitals pooled their resources in this study; the participating physicians were either Veterans Administration-based or clinical faculty members of the associated medical schools who thought the issue was important and the time ripe for such a study.

Randomized Study

The design of the trial is shown in Figure 1. Candidates for the study were detected among patients admitted to these 12 hospitals for a variety of reasons. Following initial hospitalization for work-up and evaluation, patients who were tentatively eligible were discharged to the clinic on known placebos where they were followed for a trial period of two to four months. Those who qualified for admission to the study on the basis of the findings during the initial hospitalization and during the trial period were then randomized into the study to receive either active drugs as shown here or placebos of these three drugs. Reduction of doses or omission of offending agents was permitted in case of severe side effects or excessively low blood pressure.

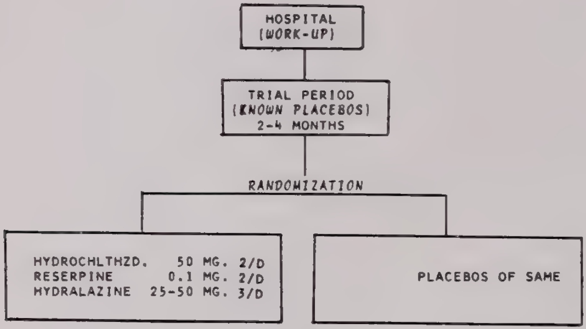

Figure 1

Severity Index

Those patients whose diastolic pressure during the fourth through the sixth hospital day averaged from 90 to 129 mm Hg and whose severity index of hypertension was less than 16 were the prime candidates for the study. The severity of the hypertension was graded on a numerical scale in which hospital basal diastolic blood pressure, and abnormalities in the optic fundi, central nervous system, heart and kidneys were combined to obtain a total "severity" index. We excluded patients who had a history of grade III or IV funduscopic changes, cerebral or subarachnoid hemorrhage, dissecting aneurysm, congestive heart failure persisting despite digitalis and mercurials, BUN ≧ 60 mg percent, and also patients with acute hypertensive-encephalopathy or a history of the same in the past. Patients with terminal diseases unrelated to hypertension, such as malignancies, were also excluded. Finally, in an effort to keep the drop-out rate as low as possible we excluded patients of doubtful reliability, such as most alcoholics and vagrants.

Reliability Tests

Further exclusions from the study proper were made during the pre-randomization trial period when the patient received placebos known to the doctor but not to the patient. During the trial period the patient was seen at monthly intervals in the clinic. In order to qualify for randomization, the average of the diastolic blood pressures observed in the clinic while on known placebos had to be in the range of 90 to 129 mm Hg. In addition, there had to be two *successive* clinic visits, in which the patient exhibited no violations with regard to several different tests of reliability. These reliability tests were: keeping scheduled clinic appointments; pill counts; and urine fluorescence tests. The pill counts had to be in an acceptable range. The fluorescence test was based on the ability of riboflavin to produce a bright fluorescence of the urine, riboflavin being incorporated in the tablets.

Risk Factors

The study started in the Spring of 1964 and by the end of 1966, 421 patients had been enrolled. By this time it became apparent to the reviewing biostatisticians that a rather large number of complications were clustering in one segment of the placebo-treated group and very few complications in the comparable segment of the actively-treated group. Various indices were used in an attempt to separate out the patients with the highest risk rate of these adverse events. Among the criteria tested were blood pressure, funduscopic changes, cardiac changes, central nervous system scores and renal severity scores. It was found that the average diastolic blood pressure measured by the doctor in the clinic during the placebo trial period provided by a considerable margin the best prognostic indication of future trouble. Optimal separation between higher-risk and lower-risk groups was obtained at a diastolic level of 115 mm Hg, those at this level and above being the high-risk group. It is this latter group with average clinic diastolic pressures of 115 mm or more during the trial period on *known placebo treatment* whose results are described. All of these patients were removed from the study one year ago and placed on known active drugs. The lower-risk group, with trial period diastolics below 115 mm, are still in the randomized double-blind trial.

The High-Risk Group

Background Characteristics

The high-risk group included 70 patients randomized on placebos and 73 on active drugs

(Table 1). How comparable were the two groups? With regard to race, the percentage of Negroes was slightly higher in the actively-treated group. With respect to prevalence of cardiac symptoms, the two groups were essentially similar. Note the high proportion of patients with enlarged hearts. However, the numbers were essentially the same in the two groups.

TABLE I
Background Characteristics

	Number	
	Placebo	Active
Total	70	73
Caucasian	35	31
Negro	35	42
Cardiac symptoms	22	21
Ungerleider abnormal	31	29
ECG—LVH	22	24
Prior CVA	5	6
Diabetes present	5	8

Table 2 shows that the two groups were also similar in other key characteristics. We have concluded that placebo and drug-treated patients were comparable in all major respects.

Blood pressure was successfully reduced in the actively-treated patients.

TABLE 2
Background Characteristics

	Averages	
	Placebo	Active
Age (yrs.)	51	50
Weight (lbs.)	183	185
Hosp. diast. P (mm.Hg)	106	107
Pre RX Clinic B.P.	187/121	186/121
Fundi grade	1.2	1.3
Renal grade	0.5	0.3

Blood Pressure Changes

Figure 2 shows the distribution of blood pressure changes at the end of the fourth month following randomization.

Ninety-four per cent of the actively-treated patients showed a reduction of diastolic blood pressure, the average fall being 28 mm Hg. The average diastolic pressure dropped from the pre-randomization level of 121 to 93 at four months.

In the placebo group half the patients showed no change. Of those who showed a change, more had a decrease in blood pressure than an increase. Observations at later time periods showed that the average diastolic blood pressure in the actively-treated group remained down, while the average blood pressure in the placebo group stayed closer to the initial level.

Because we began enrolling patients in the study in the Spring of 1964 and stopped the double-blind study on high-risk patients one year ago, we have a variable length of observation per patient — ranging from one to 34 months. The period of postrandomization follow-up was shorter in the placebo group, averaging 16 months, as opposed to 21 months in the actively-treated patients. The reason for the difference is the large number of placebo-treated patients who were removed from protocol and placed on active therapy because of complications.

Mortality

The first and simplest analysis of results pertains to the mortality observed. There were four deaths, all associated with cardiovascular complications (two dissecting aneurysms, one

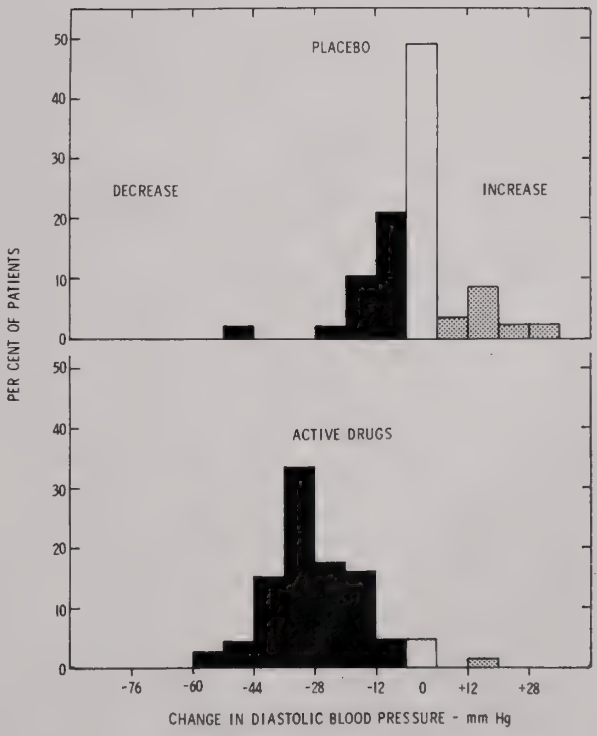

Figure 2

ruptured abdominal aneurysm and one sudden death). All occurred in the placebo-treated patients.

Morbidity

In defining the main purpose of the study, cardiovascular morbidity, two classes of morbid events were established early: Class A consisted of hypertensive complications and Class B of atherosclerotic complications or congestive heart failure responding to digitalis.

Class A events required removal of the patient from protocol treatment with permission to treat with known active drugs. Included in this category were the following: cerebrovascular or subarachnoid hemorrhage; dissecting aneurysm; a two-fold increase of blood urea nitrogen (BUN) to levels above 60 mg/dl; funduscopic evidence of grade III or IV hypertensive retinopathy (multiple striate hemorrhages or soft exudates in more than one quadrant, or bilateral papilledema); and congestive heart failure if it could not be controlled with digitalis, restricted activity, and occasional mercurial diuretics. A persistent clinic diastolic pressure of 140 mm or more followed by rehospitalization basal pressure of 130 mm Hg was also counted as a Class A event because of our apprehension that another of the Class A events just listed was imminent.

On the basis of the criteria described above, ten placebo-treated patients had Class A morbid events (Table 3). There were no Class A events observed in the actively-treated patients. Five of the events in the placebo group were based upon optic fundi observations and five were other events. Follow-up of these various patients after termination from the study has shown that eight had reversible complications—their funduscopic and cardiac abnormalities disappeared with treatment; or, in the case of the patient with marked elevation of blood pressure, the blood pressure came down with treatment with known drugs.

Active	
Hyperglycemia and depression	1

Treatment Failures

During the study it became necessary to account for an additional category of terminating events called "Treatment Failures." In such cases, the strict criteria for a Class A event was not met, but removal from protocol seemed necessary to the participating physician on ethical grounds.

There were seven "Treatment Failures" in the placebo group. These are detailed in Table 4. The only "Treatment Failure" on active drugs was of a very different character—a patient who developed serious drug reactions and was removed from the study.

There was considerable discussion as to what to do with these cases in the analysis. It appeared best to report them as marginally contributing to the overall assessment of the benefit of therapy. We thought this appropriate because it seemed likely that some of these patients would have been on the verge of Class A events, perhaps catastrophic ones, had they not been removed from the study. We are, however, reporting these in a separate category.

Class B events were those judged to be more related to atherosclerosis than to hypertension. All patients who sustained such events continued in the study. There were six in the placebo group as compared to one of the actively-treated patients. Two placebo patients had myocardial infarctions but recovered; two developed congestive heart failure which responded to digitalis and other routine measures, and there were two cerebrovascular complications. The sole actively-treated patient developed hypotensive symptoms immediately following randomization and developed a hemiparesis. He recovered from the hemiparesis and was later managed without symptoms on lower doses of protocol drugs.

Discussion

Most long-term clinical studies are troubled by losses. In examining our data to determine whether the dropouts had a significant influence on the results, we applied a most rigorous test. We assumed that the seven losses from the placebo group would have had no adverse events if they had stayed. Conversely, we assumed that all five of the losses from the active-treatment group were headed for trouble and would have had a Class A or B event if they had stayed under observation and treatment. Yet even these rigorous and rather improbable assumptions yielded a score of 27 to 7 ($P < 0.001$) in favor of treatment instead of the *observed* 27 to 2.

This is a report of a study that ended much earlier than anticipated, a study discontinued for ethical reasons with fewer patients and a shorter observation period than planned. It had been agreed at the outset that as the study progressed the accumulation of results would be kept in the hands of the reviewing statistician group and not revealed to the participating physicians unless decisively favorable or unfavorable evidence emerged requiring action. The statistician group, therefore, periodically examined the accumulated findings. To avoid making hasty judgments, the action limits were set well below the 1% level of significance. When the evidence grew to the extent reported here, the reviewing statisticians sought the advice of an independent clinical investigator who concurred that it was time to discontinue the trial among the high-risk patients.

Concluding Summary

A controlled clinical trial of the long-term usefulness of blood pressure lowering agents in preventing morbidity among male patients with mild to moderate hypertension was begun early in 1964. Random assignment of patients to treated or placebo groups was employed. The study was conducted on a double-blind basis. Criteria for most assessable adverse events were specified in advance. To minimize dropouts, careful screening, including a trial period, was employed before admission to the study proper.

A clear-cut difference between those treated with placebo and drug emerged in a rather short span of time for patients with moderate hypertension (clinic diastolics 115 to 129 mm Hg). The difference was this: only *two* adverse events occurred in the group of 73 drug-treated patients, 27 events occurred among the 70 placebo-treated patients.

It's the Law

The Right of Access To Medical Records

The Minnesota State Supreme Court amendment of the Rules of Civil Procedure changed the status of medical privilege which has existed between physician and patient. Rule 35.03, entitling Waiver of Medical Privilege and Rule 35.04, entitling Medical Disclosures and Depositions of Medical Experts, became laws effective February 1, 1968.

A Code of Cooperation has been approved by the Minnesota State Medical Association, Minnesota Hospital Association, Minnesota Association of Medical Record Librarians and Minnesota State Bar Association. The purpose of this Code is to promote understanding and cooperative action between the medical, hospital, and legal professions to provide medical information to those persons authorized to receive it; also, to produce records for court or administrative proceedings in an efficient and inexpensive manner with minimum expenditure of time by all persons concerned. Accordingly, the right of access to medical records with proper authorization is a law requiring cooperation by the medical profession.

Donald C. Mac Kinnon, M.D.
Chairman, Medical Advisory Committee

FEATURE SPECIAL

Paget-Schrotter (von Schrotter) Syndrome

This syndrome consists of sudden onset of pain, tenderness, and swelling of an upper extremity, a result of thrombosis of the axillary vein. It was described by Paget in 1875 and by Schrötter in 1884. The condition occurs in otherwise healthy individuals between the ages of 18 and 50 years with a greater preponderance for the male.

The initial symptoms are followed by nonpitting edema of the arm and occasionally of the shoulder and lower part of the neck. The right arm is most frequently involved. Superficial veins are distended and a deep thrombosed vein is usually palpable. Trauma is thought to be an important etiologic factor, although the syndrome may occur in a period of chronic cardiac failure. Differential diagnosis should exclude such conditions as thrombophlebitis migrans, an aneurysm of the aorta, and metastatic carcinoma.

The course of the disorder is benign; subsidence of the thrombosis normally occurs within two or three weeks even with conservative local treatment. Anticoagulant therapy is usually indicated as a safeguard as well as to expedite recovery.

Shakespeare's Doctors

Dr. Butts

Henry VIII's physician, Dr. Butts, appears in no professional role in the play "Henry VIII." Instead, we see him acting only as loyal political henchman to the King: just happening, either by chance or contrivance, to be in the right place at the right time to observe the Archbishop of Canterbury, Cranmer, demeaned by the councilors: an indignity Butts later reports to the King.

That Dr. Butts was not just a fictional character, however, but a licensed M.D. we learn from Goodall's Epistle Dedicatory: "Dr. William Butte, Fellow of Gonville Hall, in Cambridge, and Physician to King Henry VIII, was Anno Domini 1529, admitted into the College of Physicians. Upon which he was required to subscribe to the due observation of the Statutes of the College, and to give his promise to use his best endowments for advancing the honour and perpetuity thereof."

Editor's Note: Shakespeare's slight change in the spelling of the doctor's name is defensible on grounds of poetic license.

Civilization

If Aristotle came to life again, my guess is that what would impress him most in our civilization would not be our comforts and our gadgetry, but the progress made over the centuries in advancing basic science. Perhaps the two things that would trouble him most would be the difficulties that now stand in the way of the man who wishes, as he wished, to take all knowledge for his province, and the low standard of political competence achieved by the average American citizen.

J. P. Baxter

A big man is not one who makes no mistakes, but one who is bigger than any mistakes he makes.—Nuggets

Reducing Elevated Blood Pressure

Experience Found in a Community*

JOSEPH A. WILBER, M.D.†
J. GORDON BARROW, M.D.‡
Atlanta, Georgia

A RANDOM SAMPLE of a middle Georgia community was surveyed by door-to-door questionnaire and blood pressure measurements. All individuals with an average systolic blood pressure greater than 160 and/or average diastolic blood pressure greater than 95 were identified. Their awareness of their elevated blood pressure and any history of previous treatment for high blood pressure were determined. It was found that approximately 42% of those with elevated blood pressure were unaware of it and that only 30% of those aware of it were currently under treatment for this condition. Of those under treatment, approximately half had average blood pressures below 160 systolic and below 95 mm diastolic on the day of the survey, or possible "good blood pressure control." It was concluded that 15% of those with high blood pressure in this community were "under good control" as evidenced by the level of their blood pressure. The records of the private physicians of these subjects with elevated blood pressure were surveyed for the preceding three years. It was found that the doctors lost track within three months of 56% of the patients that they had begun on treatment, and we suspect that these patients discontinued treatment within the same period.

Follow-up Studies

We desired to see if home follow-up by a public health nurse with instructions as to the nature and care of high blood pressure, plus frequent checks of high blood pressure at home, plus re-emphasis of the importance of taking medication regularly, would improve these findings. Two hundred twenty suitable subjects of the original 630 with high blood pressure divided themselves by choice into a volunteer home follow-up group (88 subjects) and

---

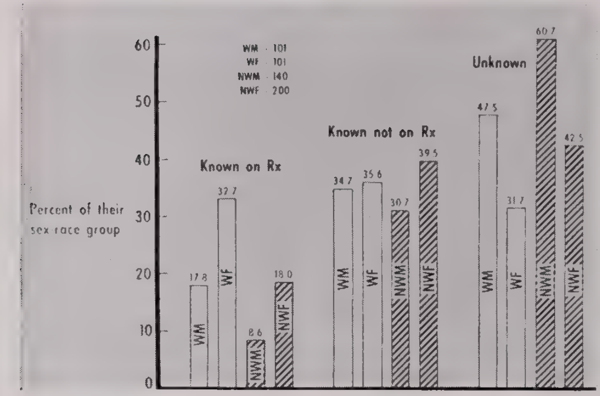
TABLE 1

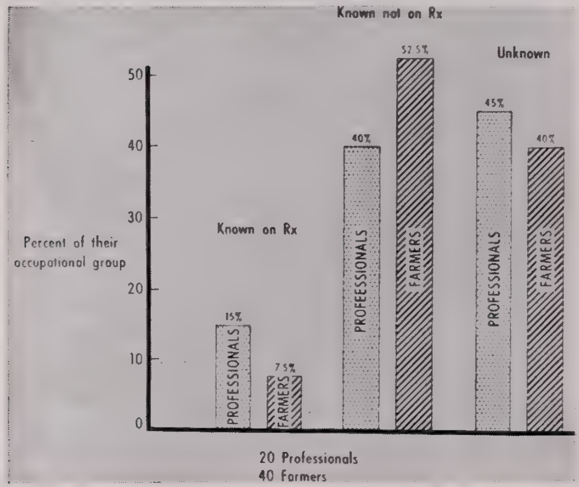


A comparison of three groups identified in a door-to-door blood pressure survey in Baldwin County. Georgia, by sex and race;

1. "Known on Rx": those who were aware of their elevated blood pressure and were currently taking medication for it.
2. "Known not on Rx": those who were aware of elevated blood pressure in the past but were not currently on treatment, (i.e., had discontinued treatment).
3. "Unknown": those who were found to have elevated blood pressure that day (greater than 160 mm Hg systolic and/or greater than 95 mm Hg diastolic) and had never known before that they had an elevated blood pressure.

WM = white male
WF = white female
NWM = non-white (negro) male
NWF = non-white (negro) female

TABLE 2



A comparison of two different occupational groups;

"Professionals" (physicians, dentists, lawyers, educators and clergymen). "Farmers"—full time occupation as self-employed farmers, by knowledge of and treatment of elevated blood pressure when originally surveyed.

a non-volunteer group (132 subjects). A public health nurse then visited the volunteers at home at regular intervals, persuaded them to go to the doctor for diagnosis and treatment and, if they were begun on medication for their blood pressure, attempted to keep them on the medication. On the average, it took two to three home visits to persuade the subjects that their blood pressure was indeed high and that they needed to see a physician for treatment. Also during the 18-month follow-up period, most of the patients had to be re-started on their medication at least once and frequently two or three times because their prescriptions ran out, or they "felt better," or they just neglected to take their medicine.

Two years after the survey the home follow-up group was compared with the non-volunteer group with regard to blood pressure level and to whether or not they were on treatment. Two years later after the entire program ended, both groups were re-surveyed to check on their persistency.

The Groups

Table 1 compares the sex and race distribution of three groups at the end of the original community survey: 1, Those that knew they had high blood pressure and were on treatment; 2, those that knew they had high blood pressure and were not on treatment; 3, those who were unaware of their elevated blood pressure. It can be seen that women are more aware of their elevated blood pressure than men and that Negroes are less likely to be under treatment than whites. Also it is evident that in both sexes and races there are very high percentages not on treatment: probably a typical distribution of the population with regard to visiting doctors' offices and following instructions. The first group are the "faithful" patients appearing in clinics and offices conscientiously; the second group come in occasionally for acute illness, and the third group are probably rarely seen in the physicians' offices or in clinics.

The Occupational Groups

Table 2 shows that in both professionals (doctors, lawyers, teachers, ministers) and farmers, there is a very large reservoir of untreated hypertension. This would indicate that educational and social levels are not all important factors in regard to awareness of high blood pressure.

The Non-volunteer Group

Table 3 shows what happened to the "non-volunteer group" of 132 hypertensives first surveyed in 1964, who were told that they had high blood pressure and were advised to seek treatment. Re-surveyed in 1966 and then again in 1968, it can be seen that the initial survey doubled the number under treatment in this group, but that when the study ended in 1966 and the public health team left the community, the number declined to approximately 35%.

The Home Follow-up Group

Table 4 shows similar findings in the "home follow-up group." This group (88 subjects), when first surveyed in 1964, showed only 25% under treatment with 15% having good blood pressure levels. By the use of home follow-up by the public health nurse with referral to a physician, education about the nature of hypertension, and reminders to take their medication, 86% were brought under treatment, of whom 80% had "good control" (diastolic levels below 95 on the average). However, when the nurse visits ended in 1966 and the subjects were left to their own devices until 1968, only 55% in that year were under treatment, with only 29% having "good control" as evidenced by their blood pressure at home.

Conclusions

There is a large reservoir of untreated high blood pressure in this population.

Forty-two percent of this reservoir is unaware of its elevated blood pressure.

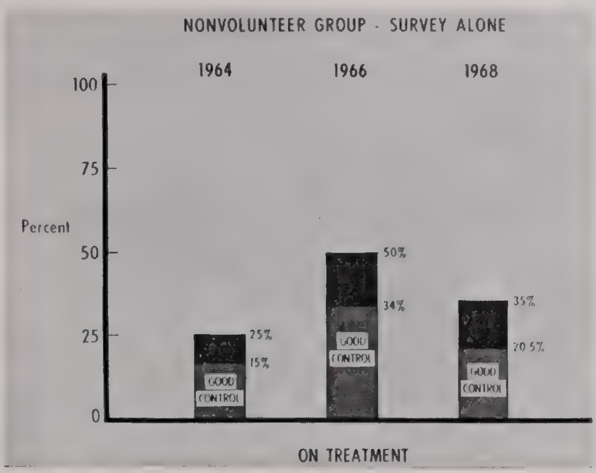
Most patients begun on treatment by their private physician are ignorant of the labile nature of high blood pressure, of its lack of symptoms and of the necessity of continuous follow-up and treatment.

Any successful program for control of high blood pressure in a community must be a continuous life-long program, must provide easy access and inexpensive or free blood pressure measurements, and probably should provide for free medication for that section of the population who feel they are unable to afford this medication.

The major reason for failure to control high blood pressure is failure to take medication.

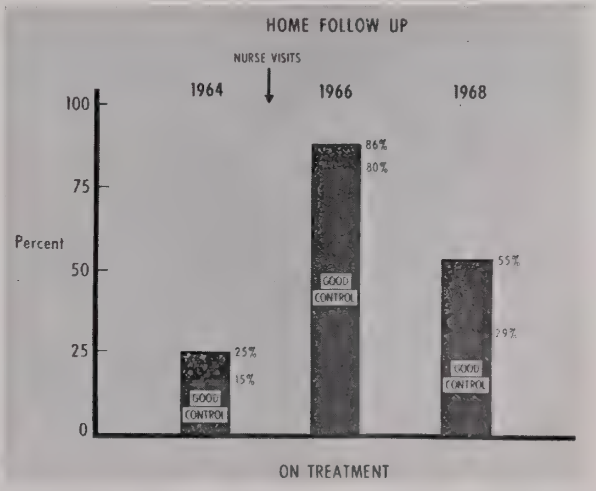
It is surmised by our study group that these results are not peculiar to Georgia but are likely to be found in other regions or countries, even those that have better educated and more affluent populations.

TABLE 3



At the time of the original survey 25% (33 subjects) of the group that did not volunteer to participate in the home treatment and follow-up program were receiving drug therapy for hypertension; 15% of these were under "good control," i.e., average diastolic B P less than 95 mm Hg. The same group was resurveyed in 1966 at the end of the community program and again two years later.

TABLE 4



The "home follow-up" group consisted of 88 subjects who volunteered and persisted in a community treatment program. This program began in 1964 and ended in 1966. From 1966 to 1968 they were again "on their own." The bar graphs indicate the percentage receiving drugs from their private physicians for hypertension, and the light areas the percentage with average diastolic blood pressures less than 95 mm Hg ("good control").

ASSOCIATE urgently needed in busy general practice. Excellent clinic and hospital facilities. Salary open. Partnership after 1 year. Klefstad Clinic, Greenbush, Minn. Call collect: Lloyd H. Klefstad, M.D., Tele. 218—782-5275 or 4725.

INTERNIST—Six physicians in corporate practice wish to increase service to area by adding general internist to its staff. Fringe benefits are available. Salary open. 150 bed open staff joint commission accredited hospital in community. Write: MINNESOTA MEDIINE—429, 375 Jackson St., St. Paul 55101.

MINNESOTA PROFESSIONAL CORPORATION with fringe benefits wishes to add a general practitioner. Full rights and privileges after one year. Joint commission accredited hospital, open staff. Write: MINNESOTA MEDICINE—430, 375 Jackson St., St. Paul 55101.

WANTED GENERAL PRACTITIONER for locum tennes in February 1970 in Cook, Minnesota. Modern hospital and nursing home, well equipped clinic. Modern spacious house to live in, car furnished. Anyone wanting to take over general practice while waiting for other assignments, this would be an ideal set up. Please call 666-2261 or 666-3354, collect if interested. Wm. C. Heiam, M.D., Cook, Minnesota.

WANTED G.P. to take over for retiring M.D. In present location for 53 years. Good business town, good churches, schools and new hospital. Not far from St. Cloud and Twin Cities. Write MINNESOTA MEDICINE—440, 375 Jackson, St. Paul 55101.

GENERAL PRACTITIONER to join two-man group, ages 35 and 38, St. Paul suburb, near lake. Excellent hospital affiliation. Estimated $30,000 plus first year, equal partner second year if mutually agreeable. Write: MINNESOTA MEDICINE—439, 375 Jackson, St. Paul, Minnesota 55101.

PRACTICE OPENING in busy, booming, Bloomington. Sports and culture opportunities; good schools, etc. Join three young G. P.'s rotating call—new ideas in medical care—Contact Richard K. Simmons, M.D., 8040 Penn Avenue So. 612-888-9211.

EXCELLENT OPPORTUNITY for General Practitioner and General Surgeon to join 5 man general practice group. Services of Radiologist immediately available. Salary open. Liberal fringes with opportunity for early partnership. College town serving population of 22,000, 30 miles from Minneapolis-St. Paul. Contact Roland M. Hammer, M.D., River Falls Medical Clinic, River Falls, Wisconsin, phone number 425-5322.

GENERAL PRACTITIONER urgently needed to join busy, well established practice in North Central Minnesota community; excellent year round recreation area, best hunting and fishing in the State. Salary negotiable for the first year, early partnership if desired. Hospital owns and maintains clinic. Call me collect. A. H. Roth, M.D., Deer River, Minnesota, office number 246-8275 or home number 246-8164.

GENERAL PRACTITIONER wanted for association leading to partnership with five Family Physicians, an Internist and a Surgeon in a modern congenial clinic environment. Rotating call schedule, ample vacation and study time. Recent deaths of two very active physicians assure an immediate practice. Community of 18,000 with excellent facilities fifty miles from Rochester and the Twin Cities. Contact: Burton A. Orr, M.D., Faribault Clinic, Faribault, Minnesota. Phone 507-334-3921.

IMMEDIATE OPENING: Internist or General Practitioner to join six man multispecialty group in northeastern Wisconsin. Excellent professional opportunity to practice in a friendly community, only two actively practicing physicians (General Practitioners) in the community outside of our clinic. Salary commensurate with training and experience first year and then full partnership. Ideal, safe small city living for the family on scenic Lake Michigan with excellent fishing, boating and hunting. All this and still only 1½ hours drive to Milwaukee or 45 minutes to Green Bay or lovely Door County. For complete details contact Robert E. Myers, M.D., Garfield at 23rd, Two Rivers, Wisconsin 54241.

Worry

A Chicago physician specializing in research on ulcers told recently that his laboratories had been obliged to abandon the use of dogs in their experiments. The fool critters just wouldn't worry—and worry is the thing that makes ulcers and keeps them active. You can inflict an ulcer upon a dog by artificial methods and he will sit down placidly and cure himself by refusing to be bothered about anything. It's just possible that there might be a lesson here for humans!

Lee Ragsdale

Modifying Elevated Blood Pressure*

A Practical Office Approach

LOUIS TOBIAN, M.D.†
Minneapolis, Minnesota

IN THE TREATMENT of benign essential hypertension, the first line of therapy consists of the use of the diuretic agents. This group includes the thiazide drugs and chlorthalidone (Hygroton®). It also includes spironolactone (Aldactone®). The thiazides and chlorthalidone are almost identical in action and side effects and can be considered together. These drugs provide very effective antihypertensive action with relatively few side effects. They lower the blood pressure not only in the upright position but also in the recumbent position. Since the diuretic drugs seem to give the smoothest treatment with the least cerebral and postural side effects, they would appear to be our best drugs. We therefore use them in fairly high doses if necessary, on the theory that we should utilize our best drugs to the fullest extent before we add somewhat less satisfactory agents.

There is no great urgency in cases of benign hypertension and we gradually build up the thiazide dosage over a four-to-six-week period. This is relatively important because the thiazide, if given in a large dose all at once, will cause a considerable drop in extracellular fluid volume and cardiac output, which will produce symptoms of faintness and fatigue and may induce the patient to stop taking the drug. However, after a week or 10 days, an adaptation occurs in which the extracellular fluid volume returns almost to normal and the cardiac output becomes normal.

Period of Adaptation

Our strategy is to give a small dose of thiazide the first week and allow adaptation to occur. The second week we increase the dose and allow the patient to adapt to the increment. During the third week the dose is again raised and adaptation allowed to occur. At this point, we can go on to fairly high dosage levels without causing the symptoms of extracellular fluid deficit.

Article previously published in GP, pp. 129-132, May, 1968. Permission given to republish.

†Professor, Department of Medicine, Division of Internal Medicine, University of Minnesota Medical School.

As an example of this type of regimen, we would start with 500 mg. a day of chlorothiazide and maintain this dosage for about a week. During the second week we would increase the dose to around 750 mg. a day. Then, during the third week, we would give about 1,000 mg. a day. We might find that the blood pressure had been lowered to an acceptable level with this dosage, and we might not raise the daily ration any further. However, if the blood pressure was not sufficiently reduced, we would then go on to 1,500 mg. a day. We would be able to do this without causing any serious feelings of faintness. In patients with very severe hypertension, particularly those with grade 3 or grade 4 eyegrounds, we might proceed to 2,000 mg. a day of chlorothiazide.

Our maximum dose of hydrochlorothiazide would be 200 mg. a day. When using chlorthalidone, we would consider 200 mg. a day as a maximum dose. With bendroflumethiazide (Naturetin®), we would consider 20 mg. the highest dose. Patients taking these diuretics are asked to restrict somewhat their use of table salt.

Sequellae

Rising Uric Acid

Difficulty is encountered in a small percentage of patients on thiazide drugs; occasionally the rising uric acid level precipitates joint symptoms. But these can usually be controlled with the addition of small doses of probenecid (Benemid®), which will lower the uric acid level to the normal range and eliminate the joint symptoms.

Low Serum Potassium

An occasional patient taking digitalis may suffer from the low serum potassium levels induced by thiazides. In these patients an additional potassium-sparing agent would be added to make the digitalis therapy smooth. We ordinarily use spironolactone for this purpose, but other potassium-sparing drugs, such as triamterene, would also be satisfactory. If a person has diabetes in his family, large doses of a thiazide may precipitate overt diabetes.

In patients with either a high uric acid level or diabetes, we prefer to use spironolactone rather than a thiazide as our base diuretic drug. Although our experience with spironolactone has been limited to only 13 months, we have the strong impression that the drug has an effective antihypertensive action and can exert this action without raising uric acid levels, without precipitating diabetes, and without lowering the serum potassium level. Moreover, it can be used concomitantly with thiazide drugs to keep the potassium level near the normal range.

We give between 50 and 100 mg. of spironolactone daily. When administering this drug, one should remember that it tends to raise the serum potassium level above normal. This is usually of no consequence, but if a patient were to be given spironolactone as well as a potassium supplement, the potassium could rise to a dangerously high level. All patients receiving spironolactone should have their potassium levels checked in the early phases of treatment to make sure that the K level is not above 6 mEq. per L. Occasionally, male patients taking spironolactone will have painful breast nipples. The pain will disappear, however, when the dose is greatly reduced.

As a general rule, we try to lower the diastolic pressure to about 100 mm. Hg. with drug therapy, providing this can be done without many side effects. The diuretics will reduce the blood pressure in at least 75 percent of patients with benign essential hypertension if these drugs are used in a fairly heavy dosage. However, there are still many patients in whom the diuretic agents do not lower the blood pressure enough.

Hypotensive Drugs

Methyldopa and Rauwolfia

If the diuretics alone have not reduced the blood pressure to acceptable levels, we add our second line of drugs to the base therapy of the diuretic drug. Our second line of drugs includes methyldopa (Aldomet®) and the Rauwolfia preparations. Of the two, we prefer to use methyldopa first, given in doses up to 1,500 mg. a day. This drug can cause some drowsiness and may even produce slight confusion in certain patients. These symptoms are bothersome but can be overcome when the dosage is reduced. Eventually a satisfactory level of side effects can be achieved. A Coombs-positive anemia has been produced by methyldopa, but this is rare. Watching the reticulocyte count will alert the physician to the onset of this condition.

Rauwolfia

The addition of Rauwolfia to the diuretics brings a further lowering of blood pressure and may reduce the diastolic pressure to the desired level. In very severe cases of hypertension we have used the diuretics plus fairly full-sized doses of methyldopa plus small additions of Rauwolfia to produce additional drops in blood pressure. But we do not like methyldopa and Rauwolfia as well as the diuretic drugs because of their cerebral effects. Rauwolfia may cause serious depression and has also been associated with peptic ulcer. However, if the dosage is kept fairly low, the cerebral effects are minimal. One advantage of these drugs is that they do not lower blood pressure by producing a marked drop in cardiac output. This is apparent because methyldopa and Rauwolfia lower the blood pressure in the recumbent position as well as in the upright position. Since these agents have more side effects than the diuretic drugs, we tend to use them as a second line of treatment. However, they combine well with the diuretics to give added antihypertensive action. Therefore, in patients with benign essential hypertension who are resistant to treatment, we often use these agents in combination with the diuretic drugs.

Vasomotor Reflex Suppression

In patients with moderately advanced benign essential hypertension, the combination of diuretics and the second line of drugs still may not reduce the blood pressure to satisfactory levels. When this occurs, we resort to our third line of drugs—the agents that act by dilating the veins (capacity vessels). Thus the action of the normal postural vasomotor reflexes is suppressed. When these drugs are having their effect, the veins do not properly constrict when a person assumes an upright posture. Therefore blood pools in the dependent veins and the venous pressure falls considerably. This slows the return of blood to the right side of the heart and causes a drop in cardiac output, the major cause of the fall in blood pressure that is associated with these drugs. Since their antihypertensive action depends primarily on a drop in cardiac output, these agents produce more side effects than the other antihypertensive drugs. This is why we prefer to use them only after the first two lines of defense in combination have proved inadequate. In spite of this disadvantage, these drugs can be very effective and even lifesaving in patients with grade 3 and grade 4 hypertension. Furthermore, if such a patient is receiving methyldopa and Rauwolfia in addition to large doses of diuretics, it may be necessary to give only small amounts of the drugs in this third category in order to reduce the blood pressure to acceptable levels.

Vasodilating Drugs

The drugs in this category—those that act by dilating the veins — include *guanethidine* (Ismelin®), *bethanidine* and the *ganglionic blocking agents*. Of these, the most satisfactory one obtainable in U.S. pharmacies is guanethidine which acts by preventing release of norepinephrine at the sympathetic nerve endings and does not block the parasympathetic system as the ganglionic blockers do. Guanethidine is a powerful antihypertensive drug and can be lifesaving when all else fails. It has certain disadvantages in that it lowers the blood pressure much more in the morning than in the afternoon, may cause severe postural hypotension, as would be expected in drugs that work on the capacity vessels, and can cause distressing diarrhea and rectal urgency. In men, it may prevent ejaculation.

Sympathetic Inhibitors

In England, Canada, Australia and New Zealand, it is possible to buy the drug bethanidine in pharmacies. This agent is somewhat similar to guanethidine and has some advantages over it. Bethanidine acts by inhibiting sympathetic action and does not prevent parasympathetic action. In this respect it is similar to guanethidine. However, it does not seem to produce the diarrhea associated with guanethidine therapy and its length of action is shorter, the effect of a given dose usually lasting about eight hours. Therefore, it is possible to give a larger dose at noon in order to combat the afternoon rise in pressure that is commonly seen with guanethidine. Guanethidine has such a long action that one might as well give the entire daily dose at one time; furthermore, the dose cannot be timed to take care of the afternoon rise in blood pressure. The relatively shorter action of bethanidine allows for an extra-large dose to combat this afternoon rise in pressure.

The ganglionic blocking agents are effective antihypertensive drugs and have saved the lives of many patients with grade 3 and grade 4 hypertension, but they have the disadvantage of paralyzing the parasympathetic nervous system. For this reason, these drugs have been superseded by guanethidine and bethanidine. However, we have used them at times to overcome the diarrhea caused by guanethidine. For instance, the ganglionic blocking drug mecamylamine (Inversine®) is constipating because it paralyzes parasympathetic action of the intestine. If small doses of this drug are given in addition to guanethidine, the diarrhea produced by the guanethidine is often alleviated. (A still better solution would be the use of bethanidine when it becomes available in this country.)

We prefer not to use guanethidine as a first drug but rather to add it to the regimens of patients who are already receiving diuretics and methyldopa. This permits us to use a much smaller dose of guanethidine, with considerably diminished side effects. Used in this way, guanethidine can be a very helpful drug.

Concluding Summary

One of the main ways by which hypertension increases mortality is through its acceleration of the processes of coronary atherosclerosis. Hypertensive subjects, both men and women, definitely have more heart attacks and angina pectoris than comparable normotensive persons. Hypertensive patients must be considered a high-risk group from the standpoint of prospective myocardial infarctions. Therefore, if an effective "anticoronary" regimen of any kind is ever developed, it should be applied to all patients with benign essential hypertension.

The Heart Besieged

True, it is not always possible to find out what subsequently happens to patients. It is not easy to locate a patient five or ten years after an operation and ask him how he is. But information is available about quite a few of them.

A shoemaker operated on by Janelidze returned to his trade and lived as he had lived before he was wounded.

Surgeon Magula's patient was a teamster. Ten years after his operation he hauled loads just as he had done before it.

Some of the patients were even called up for military service.

A stevedore who had had a cardiorraphy complained about a heaviness in the region of the heart whenever he picked up a load weighing more than a hundredweight.

After a cardiorraphy one of Janelidze's patients contracted syphilis. Then he had scurvy, and then typhus and relapsing fever, pneumonia and pleurisy. Finally, he had a bad case of influenza. All this in twelve years. Yet his sutured heart bore it all.

In 1916 Professor Grekov performed a heart operation. Six years later his patient came for a medical check. In the absence of the professor another surgeon examined him. The patient was found to be fit. He had a normal pulse, and normal heart tones. He could easily walk 30 miles and climb to the sixth floor several times a day. Only the scar on the left side of his chest, which receded a bit every time his heart contracted, reminded him of his heart operation.*

Cigarette Smoking*

The Associated Cardiovascular Risk

JOSEPH T. DOYLE, M.D.†
Albany, New York

That tobacco might exert detrimental effects on the cardiovascular apparatus seems not to have been recognized until 50 or 60 years ago when the diagnosis of tobacco angina was popular. Not until 1908 was plausible evidence submitted that cigarette smoking might be implicated in the pathogenesis of the arteriopathy now known as Bürger's disease or thromboangiitis obliterans. It was suggested that this disorder, having some of the characteristics of an acute inflammation, occurred exclusively in young Jewish males who were invariably heavy cigarette smokers. Remissions and exacerbations of the disease were strikingly related to cessation or resumption of cigarette smoking. On the other hand, DeBakey[7] concluded from observations made during World War II on large numbers of young soldiers with this disorder that the role of tobacco is not important. More recently Wessler[21] has asserted that atherosclerosis and thrombo-embolic disease adequately account for the clinical picture recognized as Bürger's disease, while McKusick[15] has vigorously and persuasively rebutted this view, citing typical examples in cigarette-smoking Orientals. How tobacco accounts for the clinical syndrome of thromboangiitis obliterans is completely unknown.

Physiologic Basis of Obliterative Disease

Cigarette smoking is generally conceded to have an adverse effect in the common variety of obliterative peripheral vascular disease. The physiological basis for this effect is well established. While muscle blood flow, as measured by the clearance of injected radiosodium, is little changed by cigarette smoking, there is a sharp curtailment of skin blood flow, measured by temperature change or by plethysmograph. Where arterial inflow is compromised, such a critical reduction in skin blood flow predisposes to ischemic ulceration which accounts for most of the disastrous complications of obstructive peripheral arterial disease. The measurable circulatory effects of smoking are attributed exclusively to the amount and rate of nicotine absorption and are acute, transient and noncumulative. Sham smoking and the smoking of denicotinized and non-tobacco cigarettes fail to produce any circulatory changes. Nicotine powerfully mobilizes catecholamines, particularly epinephrine. As a consequence, there are modest increases in heart rate, cardiac output and stroke volume and arterial blood pressure lasting 15 or 20 minutes. The effect of tobacco smoke on coronary blood flow in humans is incompletely known. In most instances consonant with the rise in arterial blood pressure and in cardiac output there is an increase in coronary blood flow. There is some evidence that blood flow may not increase in coronary obstructive disease in proportion to the rise in heart rate and in blood pressure, i.e., the time-tension index, which primarily determines myocardial oxygen consumption.

Sudden Death and Myocardial Infarction

The unfavorable influence of cigarette smoking on certain types of heart disease has been recognized only fairly recently. Incidental to the large retrospective studies of the relationship between cigarette smoking and lung cancer undertaken about 15 years ago a large excess of deaths from coronary heart disease was observed in cigarette smokers. At about this time the prospective studies of cardiovascular degeneration in Framingham, Massachusetts, and in Albany had accumulated several years' experience.[10,11] The prevalence and the preliminary incidence data showed a consistent but not statistically significant association between ischemic heart disease and the tobacco habit.

Mortality

Pooled observations were able to show a significantly larger number of cases (approaching 200%) of sudden death and of acute myocardial infarction in men smoking 20 or more cigarettes daily, compared with non-smokers. There appeared to be a gradient of risk related to the number of cigarettes smoked but not to the duration of smoking. In one million men and women Cuyler Hammond[12] has shown a mortality ratio in the 45- to 54-year-old range of 2.81 in male smokers compared with non-smokers, and in women of 2.00.

Epidemiological studies have shown a statistically significant relationship between the smoking of 10 or more cigarettes daily and the occurrence of acute myocardial infarction and sudden death. No specificity of this relationship has yet been shown. The reason for the pernicious effects of cigarette smoking continues to defy explanation.

Morbidity

Compared with non-smokers, men smoking 60 cigarettes daily had a morbidity ratio as high as three while men smoking fewer cigarettes had a lower rate. Furthermore, there appeared to be a decline towards the morbidity experience of non-smokers in men who gave up cigarette smoking. Pipe and cigar smokers had about the same experience of myocardial infarction as non-smokers. Finally, no relationship could be demonstrated between cigarette smoking and angina pectoris as a solitary clinical manifestation of coronary heart disease. The evidence which has accumulated in these two studies since the first report on smoking has reenforced the initial observations. Other prospective studies have been, in general, confirmatory.

Seltzer[18] has indicated that inversions and anomalies can be found in the newer data. In particular, the morbidity experience of ex-smokers is not so favorable as originally appeared, although the health status and the motivations of people giving up smoking may well be different now from some years ago. Retrospective pathologic studies have shown good correlation between the severity of coronary atherosclerosis and the number of cigarettes smoked.

Physical Fitness

Although cigarette smoking is condemned by athletic coaches, there is remarkably little evidence showing impaired physical fitness in cigarette smokers. Cooper[6] has, however, recently shown that during basic military training, heavy smokers have less endurance than non-smokers, although athletic training and ability are also important factors.

The possible interrelationships of cigarette smoking with other risk factors have been intensively scrutinized. While catecholamines mobilize free fatty acids, there is no evidence that the triglyceride or cholesterol concentrations in the serum of smokers differ from those of non-smokers. Body weight is not a factor. Indeed, smokers tend to be somewhat lighter than non-smokers. There is no correlation between the smoking habit and arterial blood pressure, although hypertension notoriously accelerates and exacerbates coronary heart disease. If anything, smokers tend to have lower blood pressure levels than non-smokers.

Much attention has been directed to the influence of cigarette smoking on clotting mechanisms,[16] on the Rokitansky-Duguid thesis that thrombosis initiates atheropoiesis and is certainly responsible for the ultimate catastrophic complication of occlusion at the site of atheromatous ulceration. In-vitro methods of measuring clotting are crude and unreproducible in the extreme. Probably the most suggestive evidence is that platelet turnover and platelet adhesiveness seem to be increased by cigarette smoking, and hence may favor the formation of an arterial clot. On the other hand, it is well known that obstructing clots are scarcely ever found in cases of sudden death despite the invariable presence of widespread atherosclerosis, and begin to appear with regularity only 24 hours or so after the initial catastrophe. Very recently it has been observed that in dogs exposed to cigarette smoke the threshold for ventricular fibrillation becomes subnormal for periods up to an hour.[20] If this is indeed true, it provides a convincing explanation for the high frequency of sudden death in heavy smokers. The apparent difference in reactivity of patients with angina pectoris remains puzzling. Finally, it should be emphasized that the risk of cigarette smoking becomes much attenuated after the age of 55.

Conclusions

There is convincing circumstantial evidence that heavy cigarette smokers prior to the age of 55 have a substantially higher rate of myocardial infarction and of sudden death than non-smokers, both men and women. Cessation of smoking appears to be rewarded by a reduction in risk of myocardial infarction and sudden death. The heavy cigarette smoker is, of course, also subject to chronic bronchitis and to pulmonary emphysema. Both are causes of cor pulmonale, which is a most serious complication not only of coronary but of any type of heart disease. Despite the lack of explanation for the lethal effect of smoking, there is ample evidence to justify discouraging the young from acquiring the habit, persuading the adult to abandon the practice, and to forbid, unequivocally, smoking by the victim of cardiopulmonary disease. Immoderate cigarette smoking is a special form of self-induced atmospheric pollution and as such constitutes one of the major challenges now confronting public health.

|| Smoking*

Reducing the Dangers

RONALD G. VINCENT, M.D.†
Buffalo, New York

Of the ten leading causes of death, smoking has been associated with eight of them. The ninth may well be included, if you consider the man who drives through the guardrail while trying to light his cigarette. A medical index[1] lists over one hundred diseases that are related to cigarette smoking.

The association of the cigarette habit with so many separate diseases is an indication of the complex composition of cigarette smoke. If the cigarette emitted only one noxious agent, it might be possible to identify and render this agent innocuous. The cigarette, however, emits hundreds of noxious agents, each producing its own pathophysiological effect.

Carcinogenesis

You will frequently hear from public relations sources close to the Tobacco Industry, that the association between cancer of the lung and smoking is only statistical, has not been proven, and that much more research is needed. Except for the confusion that is intentionally instilled in the public's mind, it would be hard to disagree with some of the elements of this statement.

At least thirty of the substances within the smoke either are carcinogenic or promote carcinogenesis. The components that are known to be carcinogenic are, for the most part, aromatic hydrocarbons; but these hydrocarbons represent only a small fraction of the total carcinogenic properties of crude tar derived from cigarette smoke. While there can be no reasonable doubt that cigarette smoke has a casual relationship to lung cancer, a great deal must yet be learned as to how it initiates the malignant changes.

In evaluating carcinogenesis we do have a satisfactory assay system: something not yet available in cardiovascular research. Many investigators attempted to produce lung cancer in a variety of animals and, until recently,[2] these experiments failed, largely due to the lack of cooperation by the animal involved. It is yet to be determined whether the animal's reluctance to inhale smoke is an act of brilliance or stupidity. In any event, the technical aspects of producing lung cancer were so great that it seemed desirable to develop another means of evaluating the carcinogenic properties of tobacco tar. Wynder,[3] in 1953, was able to report the first extensive production of skin cancer in mice by application of cigarette smoke condensate. Subsequently, it was observed that cigarette tars could produce tumors in a variety of animals, such as hamsters, rabbits, rats and fowls.

---

*Presented at the Minnesota Symposium on Prevention in Cardiology, May 2-3, 1968 in Rochester, Minnesota.

†Associate Chief, Department of Thoracic Surgery, Roswell Park Memorial Institute.

Convenience and economic factors ultimately decided in favor of the mouse for use in a carcinogenic assay system. Cigarette smoking machines were designed that could smoke as many as 20,000 cigarettes per day, and the tars extracted from the smoke could then be analyzed and used in biological experiments. Extraction of tars from cigarettes and the production of malignant tumors in mice by application of the tars to the skin has become a high-school biology experiment. One cannot, without reservation, apply to the human population, data obtained from experimental models that use mice; however, the more the mouse skin assay system was used, the more it seemed to correlate with human experience. For example, it has been established that the incidence of lung cancer in Scotland, England and Wales is nearly twice that of the United States. Tars extracted from English cigarettes and used in the mouse skin assay system were found to have nearly double the carcinogenic properties of the tar extracted from American cigarettes.[4]

Hazards Identified through Mouse Skin Assay

Some of the factors that make the English cigarettes so hazardous become more apparent as information becomes available through the mouse skin assay system. Ten years of experience in the use of this system now allows us to make the following general statements:

1. Daily application of the tar from about eight cigarettes causes the development of precancerous and cancerous skin lesions in mice[5] in less than one year.

2. The number of tumors and the time of development depend upon the amount of exposure to the tar. For example, repeated daily application of 50 milligrams of tar will produce approximately twice as many tumors as 25 milligrams of tar.[6]

3. Equal amounts of tar will produce tumors at variable rates, depending on the type of vegetable leaf used to obtain the tar. For example, tar from cabbage is more carcinogenic than tar from Virginia tobacco, which in turn is more carcinogenic than tar from Burley tobacco, lettuce or maple leaves.[7]

4. Flue-cured tobacco is considerably more carcinogenic than air-cured leaf.[8]

5. The carcinogenic properties of the whole tobacco tar are about two hundred times greater than the sum of the carcinogenic properties of all the known carcinogens within the tar.[9]

6. There are agents in the raw tobacco leaf, in all probability present during the combustion of cured tobacco leaf, which can promote and accelerate carcinogenesis, but which, of themselves, are not carcinogenic. Many of these agents are yet to be identified and their modes of action described.[10]

7. The known carcinogenic properties of cigarette smoke are found primarily in the particulate phase; however, substances within the volatile fractions of the smoke may well compromise the lung's ability to protect itself from harmful agents.[11,12]

8. Substantially more carcinogenic tar is delivered to the smoker if the cigarette is smoked to a very short butt (23 mm.).[13]

9. Filters vary considerably in their capacity to remove carcinogens from cigarette smoke. Effective filters are rarely found in the most popular brands of cigarettes.[14]

The Most Carcinogenic Cigarette

If it were one's intent, through knowledge presently available, to develop the most carcinogenic cigarette possible, one would incorporate in its design the following features: select a flue-cured Virginia tobacco, cut it very fine and pack it tightly into a cigarette with a paper overwrap of low porosity. (Decreased paper porosity provides for slower burning and higher temperatures, and permits a significant number of extra puffs.) Filters should not be used, or if so, one of those that are practically ineffective. Further, the user of this most hazardous cigarette should be allowed to smoke it to the shortest butt possible. The description and use of this hazardous cigarette is not unlike the manufacturing design of current English brands, or the smoking habits of the people who use them.

Cardiovascular Disease

There is, also, no reasonable doubt that smoking is related to coronary heart disease, but there are many questions yet unanswered as to how it is related. While we seek to understand the association of aromatic hydrocarbons, polonium, terpenes, crotamines, phenols, and the nitrosamines to lung cancer, we must also consider what there is in cigarette smoke that makes the platelets stickier, or alters the coagulability of the blood, or causes myocardial anoxia, or elevates the serum cholesterol and lipids. I feel confident that the cause of smoking-related heart and circulatory diseases will prove to be far more than a simple nicotine or carbon monoxide effect.

There is much that remains to be done to identify and nullify the agents in smoke that affect the cardiovascular system, but we can start by removing carbon monoxide and nicotine.

Carbon Monoxide

Carbon monoxide's great affinity for hemoglobin displaces oxygen and probably aggravates a nicotine-created myocardial anoxia. Carbon monoxide can be selectively filtered out of the gaseous phase of the smoke.

Nicotine

Nicotine, a lethal agent, which has well recognized and measurable physiological effects, can be reduced or removed by a number of techniques. Nicotine can be extracted from the leaf or filtered from the particulate phase of cigarette smoke. Selecting small leaves from the top of the tobacco plant and modifications of the curing process will also reduce nicotine. Unfortunately, when you remove nicotine from a cigarette, it deprives the smoker of an element that he craves. The most popular brands of cigarettes are those with the highest tar and nicotine ratings.

Other Vegetable Smoke Toxicity

Different forms of vegetable matter have widely variable combustion characteristics. In order to evaluate these variables, we established our own farm just outside of Buffalo, where we have grown the most commonly used types of tobacco. We have manufactured our own cigarettes, using blends of tobacco, as well as cabbage, lettuce, catalpa, petunia and sugar beet leaves. These cigarettes were then placed in the smoking machine described earlier and the tars extracted from the smoke applied to the skin of mice. Equal amounts of tar will produce tumors at variable rates, depending on the type of vegetable leaf used to obtain the tar. For example, tar from cabbage is more carcinogenic than tar from Virginia tobacco, which in turn is more carcinogenic than tar from Burley tobacco, lettuce or maple leaves.[7] I should hasten to point out that while our competitors advertise their cigarettes to be like Spring, ours are, unfortunately, more like Fall on a wet day.

The Tar Content

The longer the cigarette is, the greater the yield of tar. The further down you smoke the cigarette, the more hazardous it becomes. The 7 mm. just in front of the filter yields the greatest amount of tar per puff. In view of this, the development and distribution of an unfiltered 100 mm. cigarette is the height of irresponsibility.

The person who smokes less than a half pack of cigarettes a day has little to fear from an increased risk of either cancer or coronary heart disease. Cigarettes can be designed so as to allow an individual to smoke a pack or a pack and a half, but at the same time deliver the harmful effects equivalent to that of only half a pack per day.

Tar content of the smoke per cigarette can be reduced by wrapping the cigarette with aluminum foil to the half-way point so that it will not burn beyond that point. It is also possible to chemically treat either the cigarette paper or the tobacco in such a way as to alter the combustion characteristics so that a greater residue is produced in the ash and fewer chemicals are present in the smoke. Care must, of course, be exercised not to add something that is more noxious than that which is removed.

The Space Age Cigarette

The Tobacco Industry has responded to the public concern about the hazards of smoking by flooding the market with a series of gimmicks, about which it is never stated, but always implied, that this or that makes their particular brand safe or a little safer. The Figure shows what a future cigarette might look like if all the gimmicks were placed in one brand. Since tobacco is known to be hazardous, there should be very little tobacco in this cigarette, probably enough to light and inhale once, but behind the tobacco there must be something, perhaps lettuce.

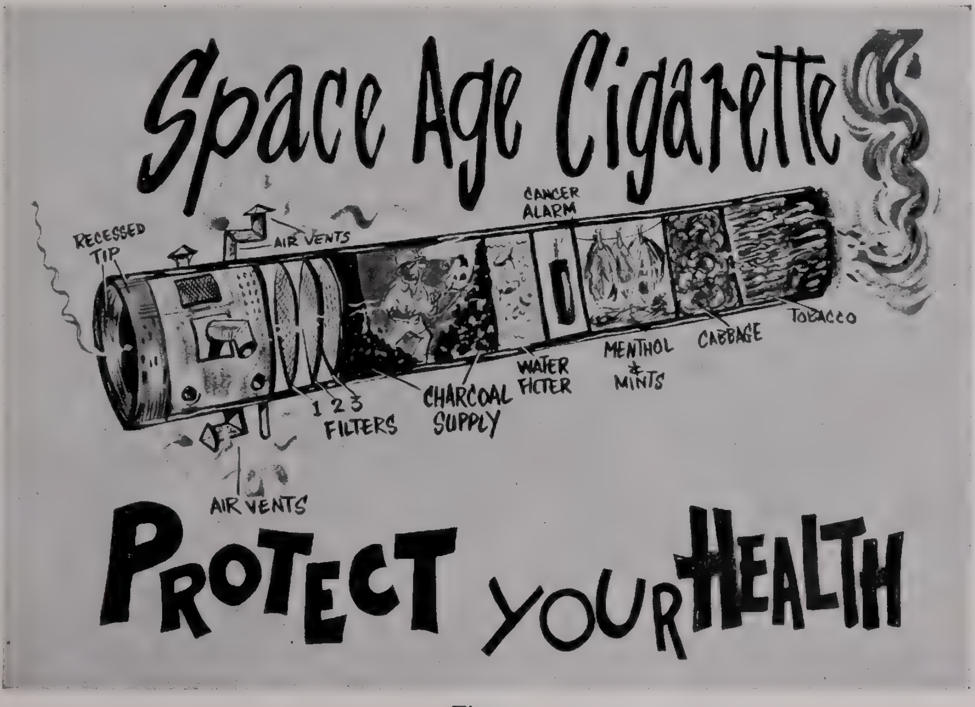
When all the pathological processes are finally identified, it may be possible to selectively remove the offending agents from the smoke. Doubtless, with the extraction or neutralization of the harmful ingredients, some of the "pleasurable aspects" of smoking might disappear, but conceivably some of them could be restored by lacing the cigarette with exotic, but innocuous, additives.

Since we are depriving the person of many of the things he craves, there should be a liberal amount of spices, mints or menthols to convince him that he is getting something. The further down he smokes the cigarette, the more hazardous it becomes; therefore some sort of an alarm system should be built in at the half-way point. The water filter, or the principle of the Turkish Hooka, is quite effective, but we never thought we would see it in an American cigarette.

However, not long ago, one brand was marketed with pellets in the filter, which if squeezed, allegedly would inundate the filter with water. There should be a liberal amount of activated charcoal, along with several filters of the cellulose type or other synthetic types now being developed. Preferably there should be air vents in the side. Obviously, if you inhale from the cigarette that has air vents in the side, you are going to get a large draft of air and very little smoke. Last is a recessed tip. To be perfectly frank with you, I don't know what this does, but whatever it is, it keeps you a quarter of an inch away from it.

Concluding Comments

It should not be implied that a significant margin of safety has been found that will



Figure

allow people to smoke cigarettes with impunity. There is some evidence that as high as our smoking-related cardiovascular disease and lung cancer rates are now, they are not as high as they would have been had we not started to use filtered cigarettes in 1955.[15] There will be no easy solutions to these far-reaching health problems, but we should seek to find means of dissuading the young from starting the cigarette habit and to encourage the adult who cannot stop to at least ease off until some more answers can be found that will provide greater protection. The cigarette can and should be redesigned, preferably voluntarily, but by legislation if necessary, to make use of the scientific data currently available. The known hazards and noxious contents of cigarettes should be clearly labeled on the pack and in all cigarette advertisements. Because of the hundreds and thousands who will suffer disability and premature death, we must continue to try to discover the exact means by which cigarettes induce disease processes and make sure that this knowledge is used as effectively and as rapidly as possible.

Heart Dignostics in Ancient Egypt

When dryness befalls his Heart, behold it is the dryness of Fire that befalls it. He sighs often and his Heart is eaten up with anger; this is because his Heart is full of Blood, which in turn is due to drinking Warm Water and eating Bad Food.

When his Heart is afflicted and has tasted sadness, behold his Heart is closed in and darkness is in his body because of anger which is eating up his Heart.

When it is Fate that he shall go Up-on-High, behold it is his Heart which determines that he shall go Up-on-High.*

Help Your Patient Stop Smoking

Guidelines for the Office Physician[*]

DONALD T. FREDRICKSON, M.D.[†]
New York, New York

THE OVERWHELMING WEIGHT of scientific evidence clearly establishes cigarette smoking as a grave threat to personal health. As physicians we forfeit an unparalleled opportunity to practice highly effective preventive medicine when we fail to warn patients and, in particular, younger patients, on the dangers of smoking. Yet recent evidence[1][‡] indicates that many physicians are not fully meeting their responsibilities on this critical health issue. In part, some of the hesitancy to speak firmly to patients about smoking may reflect an inadequate acquaintance with the evidence linking cigarettes to human disease and the benefits to be gained by quitting. I believe a far more significant fact is the physician's uncertainty as to how to approach the patient who wants to stop smoking and how to deal effectively with that inevitable inquiry: "O.K. Doctor, I believe what you say about smoking, now how do I go about stopping?" It is my intention to grapple with this and other questions related to smoking withdrawal and present a guideline that may be useful to the practicing physician in assisting his patients to stop smoking.

To be effective the physician must know where he stands on the cigarette controversy. He must be certain of his facts and formulate a clear position regarding his patient's smoking behavior. A vague, poorly defined idea that smoking is deleterious to health and somehow related to cancer will not do. For, once the cigarette issue has been raised, the patient will press with numerous questions and will expect forthright and intelligent answers. With only a hazy understanding of the relationship of smoking to cancer, respiratory disease and the cardiovascular diseases, the physician may feel uncomfortable in dealing with these and related questions. Half-hearted, watered-down instructions to stop smoking may be worse than no instructions at all. Smokers frequently search for excuses to continue smoking and may interpret uncertainty on the part of the doctor as an indication of his lack of interest or concern and an implied endorsement to continue smoking.

---

[*] Parts of this article appeared in National Forum on Office Management of Smoking Problems. Dis. Chest 54:3, 1968.

Presented at the Minnesota Symposium on Prevention in Cardiology, May 2-3, 1968 in Rochester, Minnesota.

[†] Former Director, Smoking Control Program, City of New York Department of Health, and at present, Project Director Inter-Society Commission for Heart Disease Resources.

[‡] In a recent national survey of physicians the overwhelming majority (77%) of the doctors polled agreed with the statement: "It is the physician's responsibility to attempt to convince his patients to stop smoking." An even larger proportion (86%) agreed that if a patient wants to stop smoking, it is the physician's responsibility to help him accomplish this. And yet only 38% of physicians said that they advise all or almost all of their patients who do not have any condition related to smoking to quit or to cut down.

The Public Health Service has produced an excellent summary of the 1964 Surgeon General's report[2] and has recently[3,4] updated this. In addition they have available for distribution at least six pamphlets[5] for lay consumption that persuasively argue the case against the cigarette.

Motivating the Smoker

Debilitating Chronic Disease

While it is certainly legitimate to make reference to increased death rates and elevated risks of developing cancer, the idea that by quitting smoking you significantly lower the odds of *early disability* (in the 40's and 50's) has a special meaning, particularly for the young smoker with a growing family and enlarging professional and community responsibilities. Many smokers say: "Dying doesn't bother me—after all you've got to die of something. And I calculate my chances of developing lung cancer to be relatively small." However, the idea of spending 15 or 20 years with debilitating chronic disease that interferes with the enjoyment of life and reduces ability to function is another matter. This shift of emphasis will frequently shake the young smoker out of his lethargy to the point where, for the first time, he may honestly confront himself with the thought: "Here is a problem that I have a responsibility for doing something about!"

Improving Health

Another point to emphasize is that irrespective of how long or how much one has smoked, there is everything to gain by stopping. A man with a 30-year habit may rationalize his smoking by saying: "The damage is already done—no reason to stop now!" Many intelligent people who have been smoking for many years respond with great surprise to the knowledge that if they stop, the injury associated with the smoking also stops and, because of the body's amazing recuperative powers, a significant amount of damaged tissue may be replaced or repaired.

Upper Respiratory Symptoms

It is worth discussing with all patients the *immediate* effect of smoking on the body. If an individual can begin to appreciate that each drag on his cigarette is something of a body blow to his delicate biological mechanisms, smoking may take on a heightened sense of personal relevance. Here two approaches suggest themselves. The physician can make a direct connection between the smoker's cigarettes and his symptoms — cough, morning phlegm, draining sinuses, shortness of breath, mid-day fatigue. Respiratory symptoms in particular can be legitimately and effectively tied to the cigarette habit. The physician can also give a brief description of the action of cigarette smoke on the mucociliary apparatus, stressing the importance of the cilia as the principal cleansing mechanism of the respiratory tree. The knowledge that each cigarette puff works to paralyze this delicate system will impress many smokers. The patient may then begin suggesting to himself: "Just taking this one cigarette does actual physical harm to my body."

Props

There are ways that the subject of smoking can be introduced effectively without disrupting a busy office routine. Indeed, the ability to wage psychological warfare against the cigarette habit should be limited only by the imagination and ingenuity of the doctor and his staff. Pamphlets, posters, and table-top displays may be secured from the Public Health Service or local voluntary health organizations. Ash trays should be conspicuous by their absence from the waiting room. A detailed review of smoking behavior can be incorporated into the history form—its very presence suggesting its importance to the doctor. As an example of innovative health education one physician of my acquaintance has his office nurse hand each patient a pamphlet on smoking while sitting undressed waiting for the doctor's examination. On leaving the room she remarks: "I suggest you read this; the doctor usually asks his patients about its contents." Another physician reserves his most pointed questions about smoking for the examination of the chest. As he stands behind the patient listening through his stethoscope he inquires in a serious vein: "How much did you say you smoke? For how long? Cough again, please!"

Retraining the Smoker

Learn To Be a Non-smoker

The patient should be given a rational explanation of what he must do if he is to succeed in breaking the habit. He can be told that as far as we know cigarette smoking is not a physiological addiction; rather it is a psychological addiction built upon a habit. A habit is nothing more or less than a form of *learned* behavior. If one can learn to be a smoker one can reverse the process and learn to be a non-smoker. For the discouraged and defeated smoker the idea that one can relearn or retrain oneself to be a non-smoker helps establish self confidence. No matter how downhearted the smoker may be, he is told that because he never loses the capacity to grow and learn new, more constructive, and healthier ways to behave, he never loses the ability to transform himself into a permanent non-smoker.

Motivation

Learning to be a non-smoker requires that the individual must first generate motivation. Health is the most compelling reason to stop but is by no means the only one. For example, some people stop because they are annoyed at having lost control of their habit. Others will stop not for themselves but for their family or as a positive influence for their children. Others stop for esthetic reasons; they consider the habit dirty or otherwise personally offensive. For some the economics of smoking may have significance; a 30-year habit at 5 percent compound interest adds up! And there are those who will stop in response to a challenge: they will stop on a bet! The physician should be sensitive to these incentives and appreciate that what motivates one smoker may not work for another. In counseling the patient all avenues should be explored.

The second task is to begin changing smoking behavior: the area where the physician offers his most specific guidelines. Here is the training program used in our withdrawal clinics:

The Smoking Record

The patient is instructed to wrap his pack of cigarettes in a piece of 8½-×-11 inch paper and secure this with rubber bands. He may smoke ad libitum for the next two weeks. However for *each* cigarette smoked he must complete the following procedure: unwrap the pack and note the following on the paper: a) time of day; b) the activity he is engaged in while smoking (e.g., working, answering telephone, drinking coffee or cocktails, etc.); c) his emotional state while smoking that cigarette (e.g., bored, angry, tense, nervous, etc.). He then assigns a value to the cigarette on a rating scale: I, II, III, IV, V. Each cigarette is measured against all others smoked during the day. If it is one of the most important, one that he cannot do without, it is rated I. On the other hand, if it is one of the least important, one that he could take or leave, it is rated V. All others fall somewhere in between with each succeeding category containing cigarettes of lesser importance than those in the preceding one.

This simple almost humorous instruction is one of the most powerful psychological weapons at the smoker's disposal. It should be seriously given by the physician. The patient is told that no exceptions can be made—that every cigarette is to be noted. If for some reason he feels he can't record a particular cigarette it is not to be smoked. If he "bums" or takes a puff from someone else's cigarette this is noted on the record.

The wrapping procedure is the critical first step in the withdrawal process. No further explanations are given. There are no specific instructions to reduce smoking. The patient is asked to return in one to two weeks.

On the second visit the record is collected and the patient asked to tell what he has learned about himself and his smoking. Smokers usually relate the following: (1) that simply by keeping the record he has begun to reduce his smoking. The first cigarettes to go are the III's, IV's and V's. (2) All cigarettes are not alike; they have different meanings and are used for different reasons: this is the beginning of insight into why he smokes. (3) Part of smoking is automatic, almost subconscious; there are certain cigarettes that he lights with very little awareness of what he is doing. (4) There are strong associations between cigarettes and specific activities (coffee, cocktails, after meals, etc.) as well as with certain feeling states (anger, tension, boredom, sense of well being, etc.). (5) There are but a handful of cigarettes that he really enjoys. Even heavy smokers will frequently report only three or four cigarettes in a day's consumption that are truly important.

Additional Instructions

a). Establish a pledge card. On this indicate a target date for complete cessation. Each morning pledge how many cigarettes will be smoked that day. At the end of the day record the performance, i.e., the extent to which there was success in meeting the pledge. Plan the reduction so as to be down to four or five cigarettes by the target date for stopping.

b). Develop a list of reasons for wanting to stop. Review this several times a day. Reduce it to the two or three most important reasons. In building the list we suggest concentrating heavily on the *positive* benefits of stopping.

c). Buy only one pack of cigarettes at a time. Never buy a carton.

d). Never carry cigarettes on your person. At work give them to your secretary or put them in another room. At home hide them in the cellar, the attic or the mail box.

e). Never carry matches or a lighter.

f). Hide the ash trays or fill them with cigarette substitutes, i.e., pieces of non-caloric candy.

g). Stock up on temporary substitutes—gum, low calorie candies, artificial cigarettes, etc.

h). Change brands once a week. With each change move to a lower tar and nicotine cigarette.

These instructions provide specific, concrete guidelines which support the smoker as he initiates the process of establishing new habit patterns. The list of reasons assists in focusing on motivational material. The pledge card with its target date for cessation centers the smoker's attention on a goal and provides a visual picture of his progress. The remaining instructions serve as "roadblocks" making it increasingly difficult to obtain each cigarette. This effectively interferes with the automatic aspects of smoking, making each cigarette a painfully conscious act, and provides considerable support in overcoming the urge to take those cigarettes of lesser importance. Again I would emphasize that the manner in which the physician delivers his instructions will, in large measure, determine the degree to which they are given credence and acted upon. If the physician outlines his therapeutic regime as a casual off-hand "well I don't know—why don't you try this," he will forego an opportunity to validate his therapy in the mind of the patient. If, on the other hand, he gives the instructions with an air of authority, saying in effect: "This is what you must do if you are to succeed," he will establish in the mind of the patient his belief in the *method* as well as his skill as a therapist.

Reinforce Attitude

Next to building incentive and altering behavior patterns, possibly the most important task facing the patient is to adopt an attitude that reinforces the withdrawal effort. Basically there are two attitudes the smoker can opt for. He can look upon withdrawal as a minus—an act of denial—a taking away. When he views smoking cessation in this way there is a tendency to self-pity. The longer the denial the greater the psychological distress which, in turn, often generates an intense desire to smoke. Eventually the patient gives in. Frantically lighting his first cigarette he loudly proclaims: "No one should suffer as I have," an attitude all too frequently adopted by smokers in withdrawal. It is powerfully self-defeating. The alternative is to look upon withdrawal as a *plus* in one's life. In stopping smoking you are teaching yourself a new, a more constructive, a healthier, and a more self-fulfilling way to behave. You are building into your personality a dimension of self-control and self-mastery formerly not there. From this will come a heightened sense of self-esteem.

Identifying and discussing these opposing attitudes can be helpful to the smoker and may initiate a switch from one to the other. When the attitude does change, the results are often dramatic. The smoker now looks at stopping as an exciting experiment in self-growth which may literally put a "new face" on the withdrawal program. In this context it is worth noting that the self-confidence that comes from conquering the cigarette habit may spill over into other areas of the smoker's life. When this happens he will experience an increased capacity to deal more effectively with other problems: weight control, alcoholism, work problems, etc. This we call the *ripple* effect—a substantial fringe benefit when it occurs.

Questions Smokers Ask

Once the physician has raised the subject of smoking he often finds that he has opened a floodgate, if not a Pandora's box, of questions. These inquiries must not be brushed aside nor dismissed out of hand. Responses should be formulated that are consistent with current knowledge and that will encourage and reinforce the smoker's efforts. The following are offered as examples of the kinds of questions posed and the responses that might be considered acceptable to both doctor and patient:

Question: Should I stop suddenly?

Answer: Every smoker must eventually stop completely. But why the rush? After all you didn't get into this overnight and I see no reason why you must try to get out overnight. I would suggest gradual withdrawal. This will give you small successes which will restore confidence in your ability to manage the problem. In addition, gradual withdrawal will prepare you psychologically for the time when you are ready to make a bona fide decision to stop completely.

Note: It should be kept in mind that certain types of smokers, possibly those rating high on the Tomkins-Horn "Addictive" scale[6] may have to break the habit suddenly and completely. It is my impression that it is best to let the smoker make this decision. If he feels he cannot taper off, chances are he knows what he's talking about.

Question: Why do I get so nervous when I try to stop? How long will the craving to smoke last?

Answer: Many smokers use cigarettes as they would use a stimulant or tranquilizer—to pick themselves up ("turn themselves on") or calm themselves down ("turn themselves off"), i. e., to modulate a feeling or mood state. When you suddenly take cigarettes away these feelings must be managed without benefit of the smoking "drug." This may result in a temporary though an unusually heavy load of tension and anxiety. For instance, if the smoker has come to rely upon cigarettes to 'pick himself up,' i.e., to accentuate pleasurable feelings (e.g., smoking after meals, with cocktails, during pleasant conversations, while relaxed and feeling good), he must now learn how to find enjoyment in pleasurable situations without smoking. If on the other hand he has come to rely on cigarettes to tone down uncomfortable feelings (tension, anxiety, boredom, fear, rage, hostility, etc.) he will, possibly for the first time in years, have to manage these feeling full force without the benefit of his tranquilizer. In this respect for a short period, he is very much like a steam boiler whose escape valve has been suddenly closed off. To my knowledge no ex-smoker has ever exploded!

The patient is counselled that both the nervousness and the craving are temporary and with time, measured in weeks and for an unfortunate few in months, will begin to subside. The reduction in the nervousness and craving will be the signal that retraining is taking place. It is important to stress that the acute discomfort is short-lived for the great majority of smokers. Otherwise the patient may assume that his distress will last indefinitely and conclude that this is simply too high a price to pay for stopping.

Question: What about the physical symptoms I experience when I try to stop? What causes these? Are they dangerous? How long will they last?

Answer: Smokers frequently report various physical symptoms during and immediately following withdrawal. Certain symptoms (e.g., increased cough and phlegm) may actually reflect the healing process at work. However, most appear to be physical manifestations of anxiety and tension. Examples are: shortness of breath, light-headedness, tightness in the chest, visual disturbances, sweats, headaches, gastrointestinal complaints, etc. The smoker is cautioned not to be alarmed and to look upon his symptoms as an indication that his body is actively readjusting to the non-smoking state. Our experience indicates that symptoms begin to subside within a matter of days or weeks.

Question: What can I do to avoid gaining weight?

Answer: This question is invariably asked. There is a real and for some a powerful drive to overeat during withdrawal. This may reflect a heightened sense of taste and smell and/or the lifting of a toxic effect of smoke on the gastrointestinal tract. However, it is our impression that for the most part overeating represents a substitute for cigarettes. For some the act of eating is a highly effective means of modulating psychological distress. For the occasional smoker there may be virtually a complete substitution of food for smoking, resulting in compulsive overeating and marked obesity. When this occurs I have no hesitancy to point out that the patient is really a "fraudulent" ex-smoker. He has not changed in any appreciable sense, merely switched from one mood-modifying agent to another.

There appear to be no easy answers to the weight gain problem. We advise concentrating on one habit at a time. For the moment forget weight gain. Most successful ex-smokers we have followed find that once the acute craving to smoke subsides they can bring their weight back to normal with a minimum effort. The physician should be alert to the misconception that weight gain is as harmful as smoking and if one has to choose one might as well choose to smoke. We tell our patients that to equal the harmful effects of smoking one pack of cigarettes a day one has to be grossly obese, possibly as much as 80 to 90 pounds overweight—a considerable distance from the ten to fifteen pounds gained by some smokers.

For those who will not tolerate any weight gain we suggest reducing diets. It is our experience that emphasis is best placed on alerting the patient to high caloric foods, particularly high-calorie snack foods, rather then attempting to markedly reduce the number of feedings. If eating gives relief during withdrawal it seems wise to interfere as little as possible with the act itself and concentrate attention on what goes into the mouth, selecting pacifying foods that are low in caloric content.

Question: What about hypnosis? Will it help me?

Answer: To my knowledge there have been no controlled studies with long-term follow-ups on the effects of hypnosis on smoking withdrawal though there are encouraging reports from some quarters. Consequently the best response to this query is: no one knows. One way to find out is to give it a try. If you are going to experiment with hypnosis, however, select a responsible professional who knows what he is about and what his limitations are.

Question: Are there anti-smoking drugs that will help? What about the preparations one can buy without prescription?

Answer: Three classes of drugs have been used to assist smokers during withdrawal: those which simulate the effects of nicotine (primarily lobeline compounds), those which affect the taste sensations of smoking (spicy lozenges, silver nitrate preparations, etc.), and those which modify symptoms attendant on withdrawal (stimulants, tranquilizers, and sedatives). Several well controlled studies have failed to show these preparations to be any more effective than placebos and, while there have been a few scattered reports to the contrary, there is at present no solid evidence to contradict the conclusion of the Surgeon General's 1964 report (page 354): "There is no acceptable evidence that this goal (stopping smoking) can be achieved solely by modifying sensory drives or using tobacco substitutes." Nevertheless it should be borne in mind that many smokers will respond to the placebo effect of taking anything that looks like "medication" and, when detected or suspected, the physician may wish to maximize this advantage by prescribing an inert or mild preparation in a persuasive looking form.

Question: Do you recommend switching to cigars or a pipe?

Answer: It is now clear that the risks of smoking are dose-related. Consequently anything that reduces the dose of inhaled smoke is a step in the right direction. Pipe and cigar smoke is usually not inhaled and therefore less hazardous than cigarettes. I have little hesistancy in sanctioning the transfer if the smoker feels he must have a substitute or considers the switch a necessary move toward complete cessation. It is my impression that heavy cigarette smokers who substitute cigars or a pipe stay with these for only a short period and then stop completely or revert to the cigarette habit. The patient should be cautioned that if he makes the switch and continues to inhale he is certainly no better off. It should also be noted that if the smoker suffers from peripheral vascular disease, switching to a pipe or cigar will not favorably affect his condition inasmuch as nicotine is regularly absorbed from the oral mucous membrane.

Question: Is there a safe number of cigarettes to smoke? Suppose I bring my smoking to this level, may I then continue to smoke?

Answer: For all practical purposes there is a safe level of cigarette smoking, at least a statistically safe level—under five cigarettes a day. However, I have yet to find a confirmed cigarette smoker (a pack or more a day) who has been able to bring his smoking to this level and hold it. For this reason I suspect that those who smoke five cigarettes a day have never smoked more and probably should not be classified as "smokers."

Question: Is there a filter cigarette that is safe to smoke?

Answer: There is no evidence that any filter currently on the market provides significant protection against the hazards of smoking. If a filter removes substantial amounts of the tar fraction it *may* afford some protection against lung cancer and other diseases causally related to tars. However, the degree of protection has yet to be determined. It should be noted that there are many components of tobacco smoke (gas phase) unaffected by filters. To the extent that these are related to disease, filters will have no protective value.

Reinforcement

There is little question that certain individuals will require long-term reinforcement if they are to achieve lasting success as ex-smokers. Unfortunately we know far too little about the kinds of reinforcement that will best meet the needs of different types of smokers. One suspects that, with alteration of the social acceptability to smoking, the environmental influences (mass communications, peer group pressures, etc.) which now support the cigarette habit will begin to weaken and eventually reverse themselves and support non-smoking behavior. It is also likely that to the extent that smoking becomes unacceptable in any given setting there will be reinforcement of non-smoking behavior. If for example the patient appreciates that smoking is unacceptable in the medical setting whether this be private office, clinic or hospital, and if he knows that his physician disapproves of his smoking and wants to help him stop, this should reinforce his determination to stop. This, I suggest, is one powerful argument for the banning of smoking and the sale of cigarettes in all medical facilities.

With each office visit the doctor can provide reinforcement through the simple expedient of inquiring about the patient's progress. A genuine effort to stop smoking should always be warmly applauded. The mere anticipation that an inquiry will be made by the physician and his staff can be an important source of encouragement and support.

The attitude of the patient's family is of critical importance during and immediately following withdrawal. It has been our experience that a smoker's efforts may be unwittingly sabotaged by members of the family simply because they do not appreciate the significance of his battle and consequently look upon his withdrawal efforts with disinterest if not outright amusement. A brief word from the physician to one or more of the family may be all that is needed to provide an atmosphere within the home that is sympathetic and reinforcing.

Concluding Comments

There will be those who will continue to smoke despite our best efforts. It would be unrealistic to expect the busy office physician to work "miracles" with each of his smoking patients. Nevertheless there are many whom the doctor can help—with *minimal* intervention. Just getting a patient to stop ignoring his smoking problem may be all that is needed to start him on the road to success. This can often be accomplished with one or more simple yet firm admonitions to stop. Others will require additional aid. The physician should recognize that smokers differ in the reasons they smoke and consequently in the difficulties they will encounter in giving up the habit. It is for this reason that all smokers will not respond to a single therapeutic regime—just as all patients with chest pain will not respond to one form of therapy. When the physician recognizes this he will reassess his therapy rather than fault the smoker when he fails to respond.

Finally, I would simply reaffirm what every physician knows so well—that possibly the most important determinant of success in this as in so many therapies is the physician's own behavior and attitude toward his patient and his problem. If the doctor smokes, the patient will know this and may interpret such contradictory behavior as an automatic disclaimer of anything said on the subject. He may well reason: "If my doctor really believed what he was telling me he would not be smoking himself." Like it or not, here is an issue where patients expect their doctors to practice what they preach! I submit, therefore, that it is not unreasonable to expect every physician who smokes to make a sincere attempt to break the habit.

Equally important is the physician's attitude toward his patient. Here I would put forth a strong plea for a reduction in the desk-pounding "my-God-man-use-some-will-power" approach that seems to be the prevailing ingredient of some physicians' office programs. Firmness and direction are important. Equally important are genuine empathy and understanding. Optimism and constant encouragement should be the order of the day. If the physician becomes discouraged he must diligently disguise this. It is true that to date our "success" in helping smokers (at least in withdrawal clinics) appears to have been modest. But let us remember that there are many areas in medicine where we accept modest therapeutic successes without becoming prematurely discouraged. Need we look further than cancer of the lung!

Let us also remember that with smoking, as with all addictions, repeated episodes of "falling off the wagon" are to be expected before one is home free! This may temporarily discourage the smoker but should never mislead his doctor. On the contrary, an episode of backsliding can be used effectively as a means of reopening the issue and reinforcing the smoker's determination to conquer the habit once and for all. Above all let us not forget that smoking cessation has been scientifically documented as one of the most effective forms of chronic disease prevention at our disposal. For both doctor and patient, the pay-off of becoming an ex-smoker is clearly worth a maximum expenditure of effort. As one successful smoker aptly phrased it: "The juice is surely worth the squeeze!"

Bad Health and Big Shots

The specialists inform me that almost everybody had syphilis in the sixteenth century, including Henry the Eighth, who also endured chronic, malignant wife-trouble. Charles V, Holy Roman Emperor of the German people, was strong, cautious, brave and wise, but he ate too much. If he had had a passion for Wheaties instead of roast pig the destinies of Europe might have been quite different. Samuel Pepys, whose lady-killing tendencies are now blamed on a scar in his perineum, was presumably saddled with gall stones (many eighteenth-century surgeons carried handfuls of gravel around in their pockets for display purposes if an operation failed to produce stones).

Edward Gibbon had an embarrassing what-is-it dangling around his knees, unwieldly as his Roman Empire. Martin Luther struggled along for sixty-two years with nerve trouble, ear trouble, blood trouble, and heart trouble. Henry Fielding thumbed his nose at gout and dropsy and wrote "Tom Jones" and "Amelia." Alexander Pope had spells when he couldn't stand unless laced in a frame. He averred that, at a distance, he looked like a small windmill. The mere mention of Thomas De Quincey's ailments makes hardened medicos grow pale, and yet this strange genius kept plugging for seventy-five years.*

Physical Inactivity*

The Associated Cardiovascular Risk

OGLESBY PAUL, M.D.†
Chicago, Illinois

PHYSICAL INACTIVITY is in all likelihood a cardiovascular risk factor, to be listed along with the others which have been identified over the years. Thus Fox and Haskell,[1] who made a survey of the literature, stated the following tentative conclusion: "Those who are in physically active groups have fewer manifestations of coronary heart disease than those who are not" and "The amount of physical activity needed to decrease the risk of coronary heart disease may be acceptable to many." Kannel[2] reported from Framingham: "In this sedentary population, the most sedentary had a distinctly worse outlook." He also pointed to the problems in assessing physical activity and in obtaining, for such a study, really physically active adults. Morris[3] suggested that farmers in the central part of the United States are relatively protected against coronary heart disease and that this may be in part attributable to their physically active life. Epstein[4] has also summarized the literature and has written: "The evidence is in accordance with the hypothesis that physical activity and coronary heart disease are inversely related."

It has been said that coronary heart disease is a disease of a soft exercise-free mid-twentieth-century existence. Michaels[5] in discussing this concept has pointed out that this surely does not apply to the middle and upper classes, groups which in the past never have engaged in manual labor. He points out the abundance of domestic help in England and Wales in the nineteenth century (11.8% of the labor force in 1801, 14.1% in 1901) and the number of private carriages (437,602 in 1869). He also indicates that most of the sports were spectator sports (boxing, cock-fighting, badger-baiting). Viewing this problem somewhat differently, Cumming[6] has investigated the question of the fitness of youth and has concluded: "There is no proof that the youth of today are 'softer' than the youth of previous years. On evidence presented to date, highly civilized western men would seem to have aerobic capacities equal to those of men in primitive societies."

Exercise Studies

Collateral Growth

Eckstein[7] has demonstrated, in dogs, that mild coronary arterial narrowing, as contrasted with moderate and severe narrowing, would not initiate collateral growth unless combined with exercise. On the other hand, Burt and Jackson,[8] also studying dogs but without actual coronary narrowing, concluded that exercise alone was insufficient to stimulate coronary collateral growth. Stevenson et al.[9] worked with rats and found that when the little animals were forced to run on a treadmill the coronary tree increased in size if the exercise was intermittent or only for a period of two weeks, but that when the same exercise was continued for longer periods of several weeks, no increase in coronary tree size was demonstrable.

Biochemical Changes

Nordoy, Newland, and Hamlin[10] studied the effects of treadmill exercise, both acute and long-term on rats fed a 40% butter diet. They reported that except for an increase in free fatty acids in acutely exercised rats, no changes were found in total cholesterol, phospholipids, triglycerides, and free fatty acids in the plasma. There was no difference in the incidence of adenosine diphosphate-induced thrombosis in the three groups with acute exercise, chronic exercise, and no exercise.

On the other hand, Nikkila and Konttinen,[11] studying 40 army recruits, found that after acute exercise the serum triglycerides were lower than in the non-exercised group. Dalderup, deVoogd, Meyknecht, and denHartog[12] reported that prisoners who exercised regularly achieved a slight reduction in serum cholesterol as compared with prisoners who did not participate in the program. Unfortunately, details as to the selection of the exercised and control groups are missing. Hoffman, Nelson, and Goss[13] found that the Canadian Air Force exercise program seemed to result in lower serum cholesterol and triglyceride levels in a population of Army officers. The differences reported were indeed minimal (cholesterol 213 in the exercised group, 223 in the controls, with triglycerides of 100 and 113 respectively). No true control group existed and the amount of weight change was not stated. Varnauskas, Bergman, Houk and Bjorntorp[14] studied nine patients with coronary disease in a four-to-six-week program of bicycle exercise and observed that exercise did not influence the serum level of cholesterol or triglycerides; indeed the cholesterol at the end was actually higher in five of the nine participants. McDonough and Hames[15] have suggested that seasonal variations in cholesterol levels in white and negro males were inversely related to exercise, but Thomas[16] did not find this to be the case in a population of Maryland prisoners.

Arteriographic Changes

Hellerstein et al.[17] reported that one patient developed, on repeat coronary arteriogram, clear evidence of an increase in coronary collateral circulation coincident with an exercise training program. A second patient in the program apparently showed marked clinical benefit and no coronary arteriographic evidence of the development of "an increased collateral circulation" although no control arteriogram was available.

Psychological Benefits

There is no controversy regarding this. All agree that regular physical activity leads to an increased sense of well being, more self confidence, and improved physiological measures of exercise tolerance. McPherson et al.[18] have recited some of the psychological benefits of an exercise program in 45 adult males, 18 of whom had experienced acute myocardial infarctions.

Pathological Evidence

Morris and Crawford[19] noted in 1958 that, on review of 3800 necropsies performed from 1954 to 1956 in Great Britain on males aged 45 to 70 dying non-coronary deaths, presumably ischemic myocardial fibrosis was commoner in those who had been engaged in light occupations than in those engaged in active and heavy occupations. It is interesting, however, to review the whole series of nearly 5000 autopsies available to them, which includes 1148 individuals dying from coronary heart disease (Table 1). When one does this, it is apparent that very modest differences are seen in the prevalence of coronary heart disease in the categories of latest employment described as light, active, and heavy.

TABLE 1
Frequency of Coronary Heart Disease (CHD) in Autopsy Reports on Men Aged 45-70
(1958 Brit. Med. J. *ii,* 1485)

Item	Activity, Last Job Light	Active	Heavy
Total autopsies	1922	1865	1092
Dead from CHD	482	436	230
Old infarcts, dead from other causes	51	28	10
Total CHD	533	464	240
CHD prevalence	27.7%	24.7%	22.0%

Epidemiologic Studies

There have been many epidemiological studies reported which appear to indicate that persons engaged in considerable occupational or recreational physical activity have a lessened prevalence and incidence of coronary heart disease; but not all such studies have reached this conclusion. Chapman et al.,[20] in a prospective study of 955 civil servants, found an excess of new coronary cases among those taking part in heavy physical exertion. However, their findings were based on only 37 new cases. Forssman and Lindegard[21] in 1958 studied a group of 66 males under 55 who had survived a myocardial infarction, compared them with 62 matched controls, and reported no differences in occupational physical activity. In 1960 Stamler[22] studied the mortality data in Chicago for the years 1951 and 1953 and wrote: "No specific occupation group differences in age-specific arteriosclerotic heart disease death rates were observed for middle-aged men." Pell and D'Alonzo[23] in 1961 studied 653 employees with myocardial infarction employed by the duPont Company, and found that the highest disease rate occurred among the lower middle salary group, whereas the lowest rates did not occur among those most physically active at work. In 1962, Acheson[24] was unable to observe any relation of physical activity before retirement with coronary disease as studied in a population of 221 men aged 65 to 85 years. Keys et al.,[25] studying clump samples in rural Finland, Holland, Yugoslavia, Italy, and Greece in 1966, found it very difficult to distinguish the roles of physical activity and socioeconomic status. Keys has shown that the more physically active Finns have more coronary deaths than we do (Table 2). Malhotra,[26] reporting from India in 1967 regarding railway employees, appeared to find a lower mortality among clerks than among more physically active sweepers and fitters.

TABLE 2
Deaths Per 100,000 Men 40-59
Age-Adjusted to U.S. White Age Distribution

Cause	Data	U.S. White	Finland
All causes	WHO 1962	1002	1165
Coronary (B26)	WHO 1962	371	405
All causes	Cohort*	922	1363
Coronary	Cohort*	308	421

*Five-year follow-up data from Keys, Taylor, Karvonen et al.

What about the studies which have reported a lessened morbidity or mortality from coronary disease in physically active populations? Breslow and Buell[27] in 1960 stated: "A gradient of decreasing mortality rates from coronary heart disease with increasing physical activity of work in middle-aged men . . . is confirmed under special conditions in California data for 1949 to 1954. The California gradient is clearly revealed only in contrasts between occupational groups of similar general mortality risk." They further state: "The recorded mortality data used here will not answer the question whether a limitation of physical activity is a real cause of coronary heart disease. Nor will it even provide a good estimate of the strength of the association between the two . . ." In a survey of 2240 letter carriers and postal clerks which he reported in 1963, Kahn[28] concluded: "The coronary heart disease mortality risk for those in sedentary work is between 1.4 and 1.9 times the risk of those who are more active on the job. . . ." The impact of this conclusion is blunted when we read in the next paragraph: "It is entirely possible that the differences observed are only coincidentally related to physical activity differences and that indoor versus outdoor activity, differential proportions of cigarette smokers, original basis of selection and so on are the really meaningful factors." This important matter of the original basis of selection is well illustrated by the analysis of the sedentary London bus drivers and the more athletic conductors described by Morris[19] as indicating the favorable coronary lot of the latter. As reported in 1960 (Table 3)[29] we find that the happy lot of the conductors actually may have been because they were less heavy and had less adiposity, lower serum cholesterol levels, and lower blood pressures.

TABLE 3

Mean Values, and % of Men Hypertensive, for London Busmen. D = Drivers, C = Conductors.
(1960 Proc. Roy. Soc. Med. 53, 18)[29]

	Ages 40-49		Ages 50-59	
Item	D	C	D	C

Serum cholesterol	249	228	254	238
% with B.P. 160/95 or more	10%	4%	29%	16%

In recent articles[30] Frank, Weinblatt, Shapiro and Sager have reported observations on some 110,000 participants of both sexes in the Health Insurance Plan of Greater New York. They reported: "A striking association between physical inactivity and early mortality from initial myocardial infarction in men less than 65 years of age has been shown." The data were derived from the first clinically manifest infarctions occurring in a population of some 55,000 male adults enrolled in the Health Insurance Plan of Greater New York during an observation period of 18 months (301 cases). Frank et al. also reported: "Physical activities off the job have been shown to play an important role in the relationship." I have not subjected their study to a penetrating analysis, but I am grateful to Dr. Ancel Keys for a valuable critique of this investigation. His analysis of the data leads him to have significant reservations regarding the conclusions cited above. His reservations pertain especially to problems in mail response vs. interview methods, the distribution of certain men whose physical activity was unclassified, and the existence of associations of levels of physical activity with race and religion.

In our Western Electric prospective study[31] we have 1719 men originally aged 40 to 55 who have now been followed for eight years, with the development of 24 coronary deaths, 53 infarcts with survival, and 80 cases of angina pectoris. To assess the validity of the Company codes for physical exertion in our shop population, Bliss and Graettinger[32] in 1964, using a random selection, studied 18 men in the shop working at a Code 2 level and 18 others working at a Code 4 level, using an impedance motor pneumotachograph. It was found that the men in Code 4 did indeed expend over 50% more calories than the men in Code 2. At the end of eight years there was no significant difference in the incidence of myocardial infarctions with survival in the shop and office groups as a whole, and only a slight and statistically insignificant difference of coronary deaths, with fewer being seen in the shop than expected (11 deaths as compared with 13 expected) (Table 4). After eight years, the more active Code 4 indeed

TABLE 4

		Non-Coronary	Angina	Infarct	Coronary Death	Total
Shop Code	1)	7	0	0	0	7
	2)	606	21	19	8	654
	3)	241	16	6	3	266
	4)	54	4	6	0	64
	5)	2	0	0	0	2
Office Code	1)	494	34	17	10	555
	2)	127	4	5	3	138
	3)	28	1	0	0	29
	4)	3	0	0	0	3
Total		1562	80	53	24	1718

showed fewer coronary deaths than the less active Code 2, but unfortunately also relatively more infarctions with survival.

Concluding Comments

There are basic difficulties with all such data, including our own:* the modest differences in occupational and non-occupational physical activity and the need to assess non-occupational physical activity, validation of questionnaires, the problem of occupational withdrawal, the distribution of risk factors in sedentary and physically active populations, and the differences in socioeconomic status. Suffice it to say that this list is incomplete. I should like to stress that we have no need to hedge regarding the epidemiological and other data relating hypertension and elevated serum cholesterol levels and also the heavy use of cigarettes to coronary disease and its complications. These associations have been decisively and repeatedly demonstrated.

I like physical activity. I believe it makes us and other patients feel better. I agree that it may contribute to the development of a collateral circulation in the myocardium and may be helpful in achieving satisfactory blood lipid levels through weight loss. However, the total evidence that regular vigorous physical activity per se lessens the likelihood of the development of coronary atherosclerosis and its complications is as yet not as impressive and as convincing as one would expect from the statements made by some of our scientific leaders and by statements in the mass media.

With our current knowledge of risk factors, any contribution made in minimizing the coronary problem through a routine of moderate regular physical activity is probably modest. It is possible that truly vigorous exercise, undertaken on a faithfully regular basis, may give more promising results; but we need more evidence of this.

---

*I strongly suspect that in our study the men who do the heaviest work actually smoke more. We also have evidence in our population that men who moved out of jobs requiring the most vigorous effort later developed coronary disease.

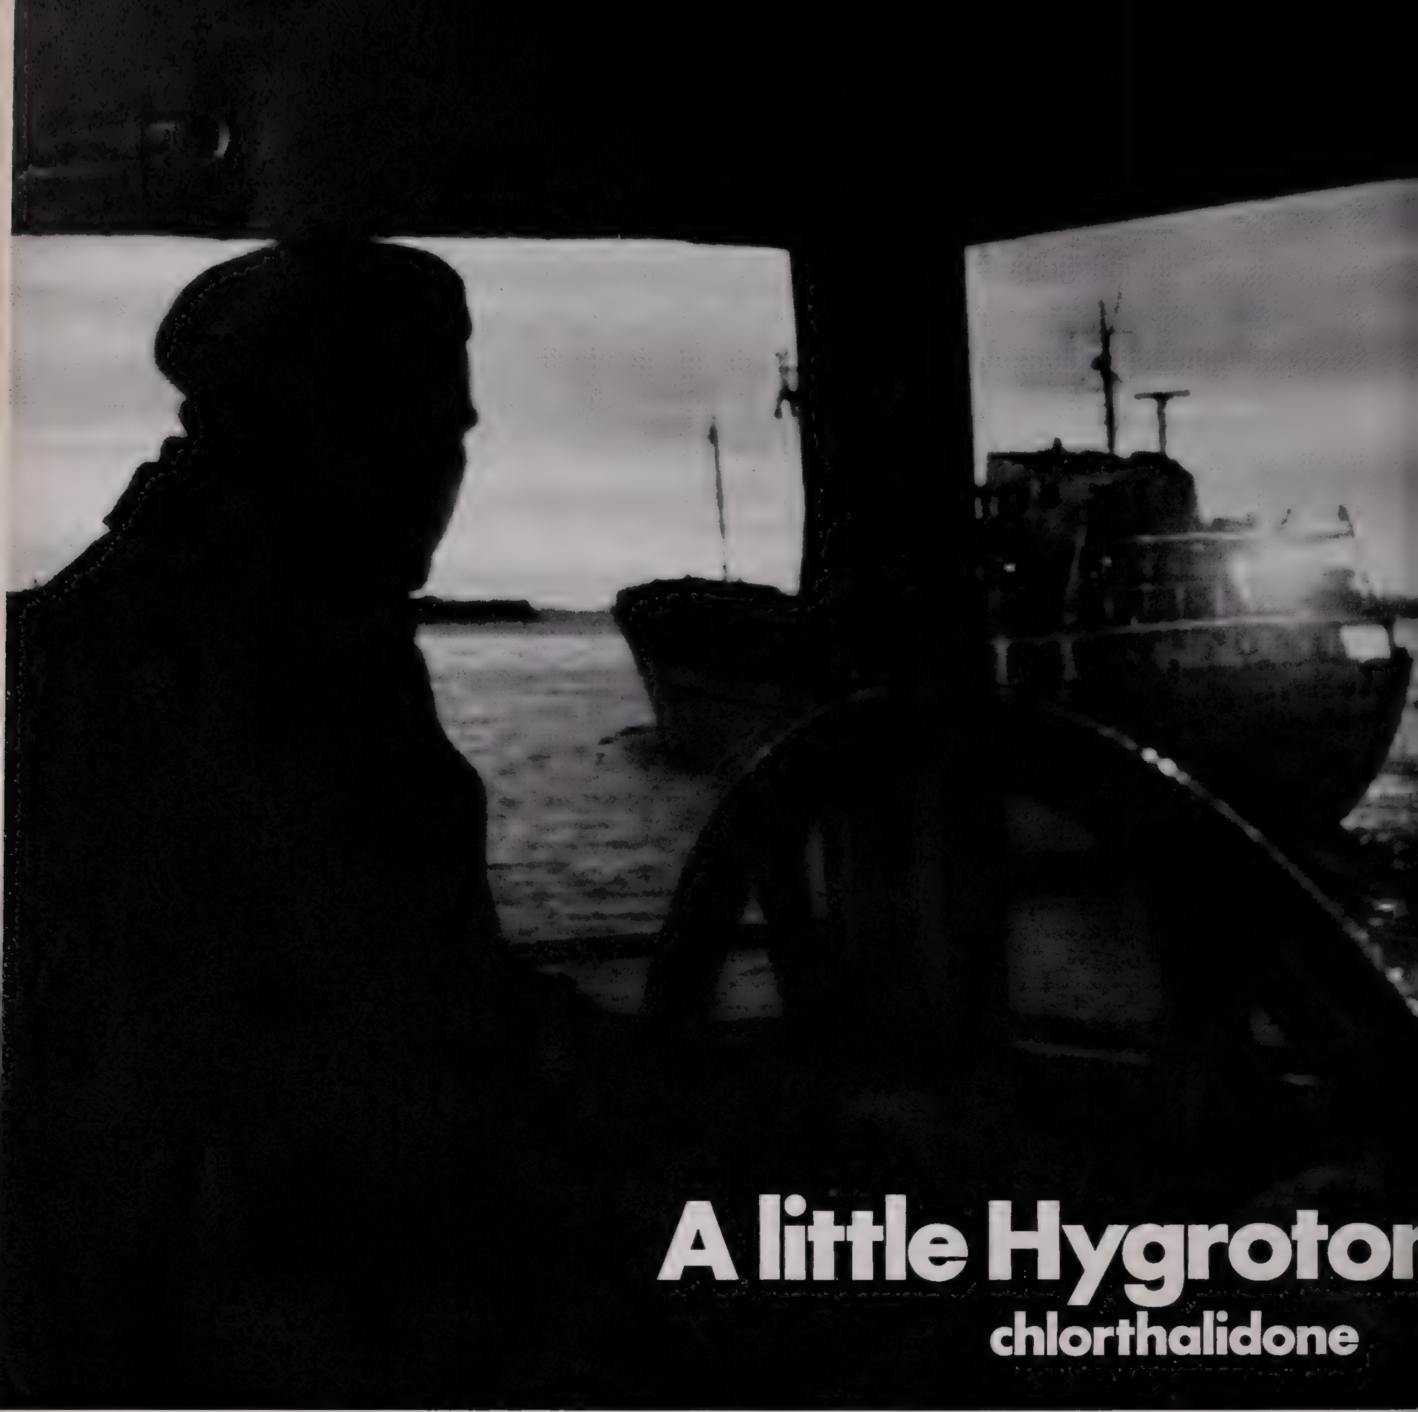
Thought

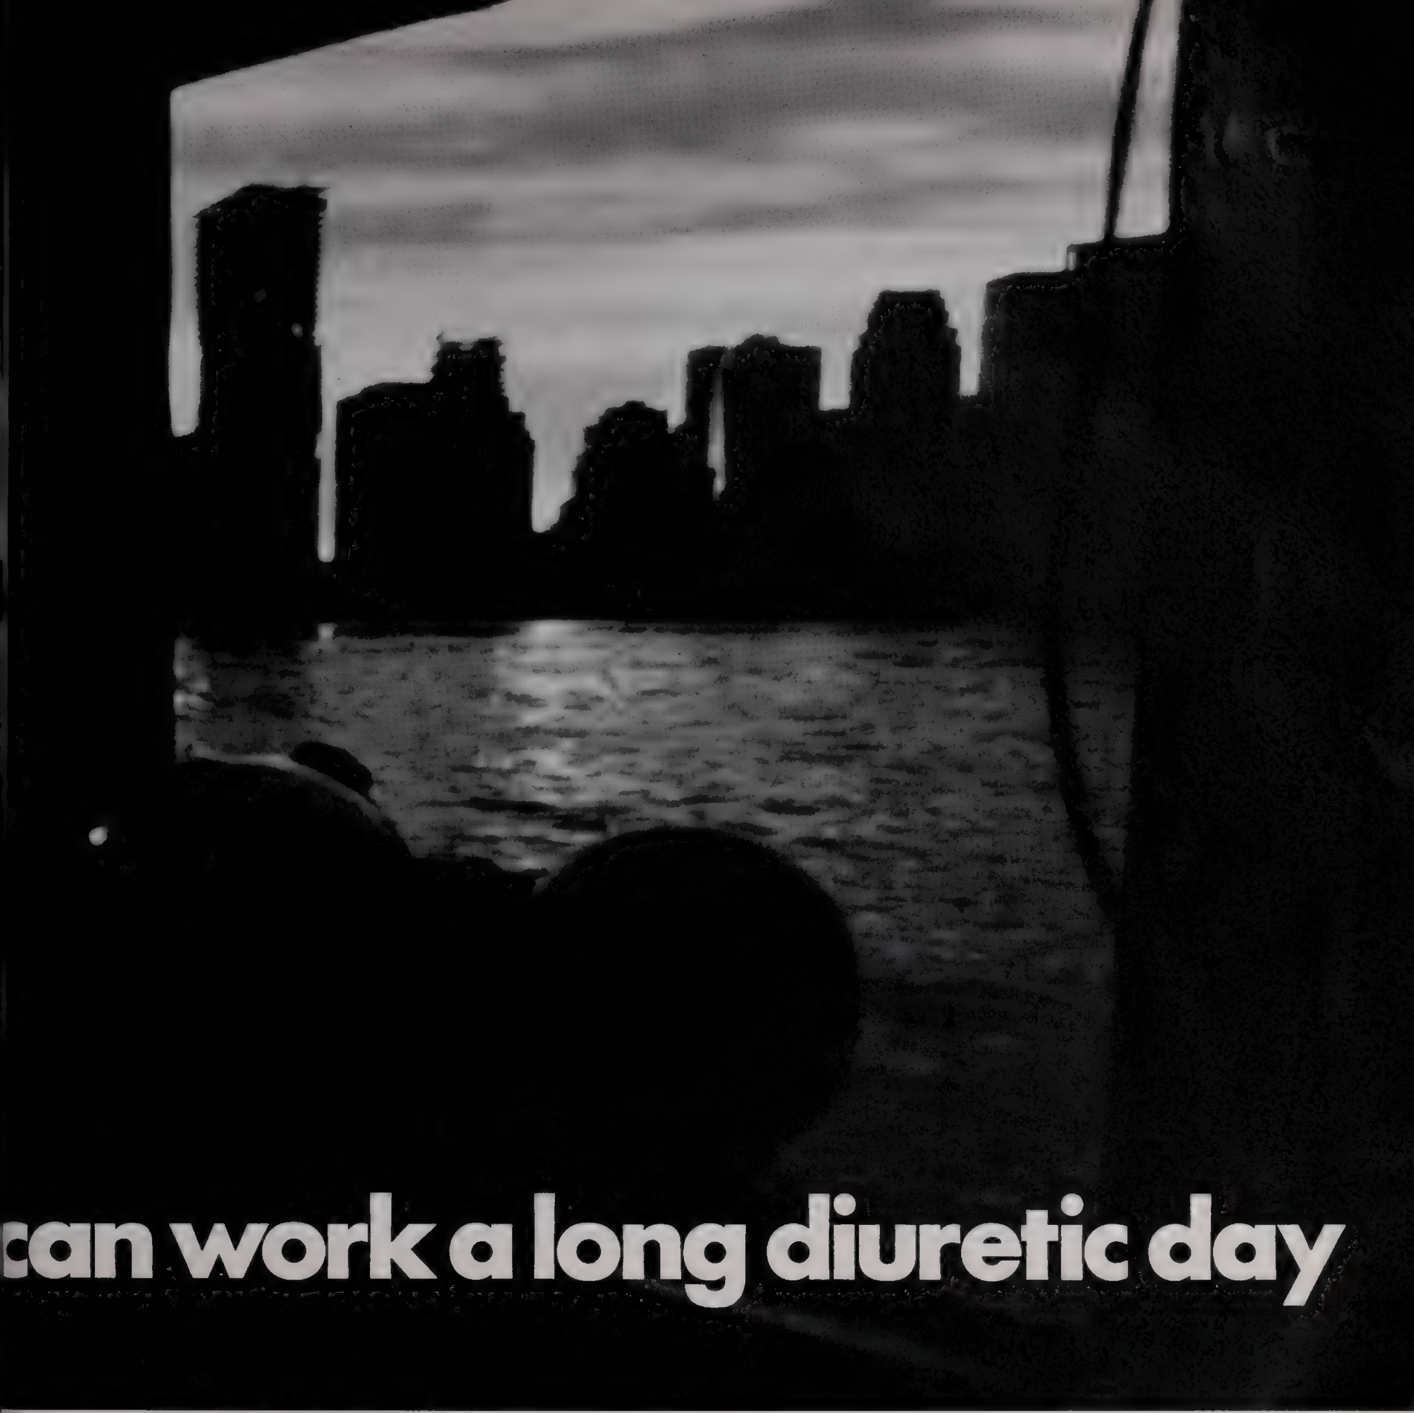
No one deserves the name of thinker until he dare think forbidden thoughts. We all do, but few of us dare admit it to ourselves. For the capacities of the human mind are limitless, and to try to limit them by a high board fence of veto, taboo, or dogma, is an attempt to rope off a stellar galaxy as a sheep pasture.

—Boston Globe



A little Hygroton
chlorthalidone

HY-6674



ll the way from one daily tablet to the next
o help control edema and hypertension

s prolonged action usually provides smooth, sustained diuretic
ffectiveness; real one-a-day dosage, right from the start; convenience
nd economy.

ygroton, chlorthalidone, can cause side effects. And it's contra-
ndicated in hypersensitivity to the drug and severe renal and
epatic diseases.

heck the prescribing information. It's summarized on the next page.

Geigy

A little Hygroton® can work a long diuretic day

chlorthalidone

Indications: Hypertension and many types of edema involving retention of salt and water.

Contraindications: Hypersensitivity and most cases of severe renal or hepatic diseases.

Warning: With the administration of enteric-coated potassium supplements, which should be used only when adequate dietary supplementation is not practical, the possibility of small-bowel lesions (obstruction, hemorrhage, and perforation) should be kept in mind. Surgery for these lesions has been required frequently and deaths have occurred. Discontinue enteric-coated potassium supplements immediately if abdominal pain, distention, nausea, vomiting, or gastrointestinal bleeding occur.

Use with caution in pregnant women and nursing mothers since the drug may cross the placental barrier and appear in cord blood and since thiazides may appear in breast milk. The drug may result in fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions which have occurred in the adult. When used in women of childbearing age, balance benefits of drug against possible hazards to fetus.

Precautions: Antihypertensive therapy with this drug should always be initiated cautiously in postsympathectomy patients and in patients receiving ganglionic blocking agents, other potent antihypertensive drugs or curare. Reduce dosage of concomitant antihypertensive agents by at least one-half. Because of the possibility of progression of renal damage, periodic determination of the BUN is indicated. Discontinue if the BUN rises or liver dysfunction is aggravated. Hepatic coma may be precipitated.

Electrolyte imbalance, sodium and/or potassium depletion may occur. If potassium depletion should occur during therapy, the drug should be discontinued and potassium supplements given, provided the patient does not have marked oliguria.

Take special care in cirrhosis or severe ischemic heart disease and in patients receiving corticosteroids, ACTH, or digitalis. Salt restriction is not recommended.

Adverse Reactions: Nausea, gastric irritation, vomiting, anorexia, constipation and cramping, dizziness, weakness, restlessness, hyperglycemia, glycosuria, hyperuricemia, headache, muscle cramps, orthostatic hypotension, which may be potentiated when chlorthalidone is combined with barbiturates, narcotics or alcohol, aplastic anemia, leukopenia, thrombocytopenia, agranulocytosis, impotence, dysuria, transient myopia, skin rashes, urticaria, purpura, necrotizing angiitis, acute gout, and pancreatitis when epigastric pain or unexplained G.I. symptoms develop after prolonged administration. Other reactions reported with this class of compounds include: jaundice, xanthopsia, paresthesia, and photosensitization.

Average Dosage: 50 or 100 mg. with breakfast daily or 100 mg. every other day.

Availability: White, single-scored tablets of 100 mg. and aqua tablets of 50 mg., in bottles of 100 and 1000.
(B)46-230-E

Franklin Plotkin, M.D.
John D. Radke, M.D.
Raymond Ricklin, B.S.
Stephen H. Salzman, M.D.
Oliver Winkler, M.D.

In the past six to seven years, my associates and I have been engaged in a prospective study to determine the feasibility and efficacy of activating habitually sedentary, lazy, hypokinetic, hypercholesterolemic, cigarette-smoking, hypertensive, overweight males, with or without manifest coronary artery disease, to participate in and adhere to a program of enhanced physical activity.[1] We hoped to determine whether such a program would be associated with some evidence of retardation of the effects of atherosclerosis, as manifested by a reduction in morbidity and mortality of coronary-stricken subjects and in the incidence of new thrombotic episodes in highly coronary-prone subjects. Therefore, the study population included both coronary-stricken and normal coronary-prone subjects. The inclusion of the latter was predicated upon the findings of prospective epidemiologic surveys.[2]

Design of the Study

The intervention program was multifaceted, the details of which have been presented elsewhere.[1,3] Emphasis was placed primarily on the enhancement of physical fitness. Physical reconditioning was a part of a comprehensive positivist program which included the improvement of nutrition, reduction of the intake of saturated fats, attainment of normal body weight, adequate rest and sleep, abstinence from the use of tobacco, and continuation of a gainful employment and of a normal social mode of life.

Methods

The evaluations were multidisciplinary and included the following data: detailed cardio-

Presented at the Minnesota Symposium on Prevention in Cardiology, May 2-3, 1968 in Rochester, Minnesota.

†Associate Professor, Department of Medicine, Western Reserve University, Lakeside Hospital, Association Physician, University Hospitals of Cleveland.

vascular history, physical examination, height, weight, somatotype, skin-fold measurements, estimation of obesity, serum cholesterol and triglycerides, timed vital capacity, psychological tests, resting and exercise electrocardiograms, and bicycle exercise ergometry. The majority of the participants were monitored for 48 consecutive hours by means of a portable electromagnetic tape recorder in order to characterize their responses to the stresses of everyday life activities.

Exercise Testing

Submaximal exercise testing on a mechanically braked bicycle ergometer (Monark, Sweden) consisted of intervals of six minutes of exercise alternating with four minutes of rest.[1,3,4] Work loads were progessively increased by increments of 150 KPM/min for each interval until a heart rate of 150 per minute was reached in the last two minutes of exercise. The electrocardiogram and arterial blood pressure were recorded at minute intervals throughout the pre-exercise, exercise, and recovery periods.

Physical Fitness

Physical fitness was characterized by the physiological variables, heart rate, blood pressure and their derivatives: heart rate × systolic blood pressure, Work Load 150, and predicted maximal oxygen uptake. Predicted maximal oxygen uptake per kilogram body weight (ml O_2/kg B. W./min) was calculated according to the method of Åstrand.[5] Work Load 150 per kilogram body weight (WL 150 KPM/kg B. W./min) was calculated according to methods previously described.[4] A minimal heart rate of 135 was used to extrapolate to Work Load 150. An indirect measure of myocardial oxygen consumption was obtained from the product of heart rate and systolic blood pressure computed for the last minute of exercise at each work level.[4]

Electrocardiogram Evaluation

Electrocardiograms were analyzed according to the methods of Lester et al.[6] in terms of the ST-J displacement and the slope of the first 0.08 seconds of the ST segment.[7] We considered quantitation of the electrocardiogram response to be important, since Robb and Marks[8] have reported that the prospective mortality rate was directly related to the magnitude of the displacement of the ST segment with a zero or negative slope. The electrocardiograms were evaluated in the same manner and comparisons between tests were made for the same load at identical external work loads.

The Subjects

The subjects of the intervention study were white, middle-aged, middle and upper class men who were referred to the program by their physicians. They continued to look to their private physicians for their overall medical care. At the onset of the feasibility study, we made no attempt to gather a true random sample or a "control" group. Our comparison group consisted of 194 coronary-stricken, age, sex and color-matched subjects concurrently evaluated in a work classification clinic. They were followed over the same period of time as the intervention subjects.

Of the 656 subjects in the intervention program, 402 were categorized as normal coronary-prone subjects, and 254 as having coronary heart disease (angina pectoris documented myocardial infarction or both). None had congestive heart failure. The coronary-stricken subjects have been followed for a total of 697 subject years, with an average of 2.7 years. At the time of the intake into the study (documented myocardial infarction, or both) the average age of the normal coronary-prone was 45 years and of the coronary-stricken 48.8 years; since the age of 25 years, the body weight had increased on an average of 19 pounds; 28 per cent of the subjects were more than 15 per cent overweight. The overall physical fitness was low and averaged 25 ml. oxygen/kg.B.W. Thirty-two per cent of the subjects were professionals (physicians, dentists, engineers, pharmacists, lawyers), 22 per cent managerials, 20 per cent businessmen and executives, 17 per cent salesmen, and the remainder semi-skilled workers. Only one per cent was unskilled. They worked more than 50 hours a week. Forty-seven per cent smoked cigarettes. Seventy-two per cent possessed the behavioral characteristics of Type A personality, classified according to the method of

Rosenman and Friedman.[9] In general, their scores on the depression (D), hypochondriasis (HS) and hysteria (HY) scales of the Minnesota Multiphasic Personality Inventory were elevated.[1]

Methods of Conditioning.

Following the evaluation of each subject, a program was formulated to enhance his overall fitness. The subject met with a study physician and a physical educator who reviewed with him the results of all tests performed, answered any questions, and prescribed for him a specific exercise program. The exercise prescription, consisting of walking, running and calisthenics, was compounded to stress each subject at approximately 60 to 70 per cent of his aerobic capacity.[4] The caloric expenditure of full participation totalled approximately 400 calories per hour. Calisthenics required 200 calories over a 30-minute period, run-walk sequences, 120 calories over a 15-minute period, and recreation, 80 calories over a 15-minute period.[1] The normal coronary-prone and coronary-stricken subjects participated in the same calisthenic groups, each following his own prescription. There are 21 lay exercise leaders, of whom five are coronary-stricken subjects.

In addition, the subjects were advised to be active physically, to climb stairs, to avoid the use of the elevators, to walk instead of riding a vehicle, to park further away from the parking lots, etc.

Each subject was encouraged to attend exercise classes at the Jewish Community Center of Cleveland at least three times a week. The subject kept a record of his attendance and made a note of comments or reactions to the exercise program. A staff physical educator examined the records kept by the subject at monthly intervals and determined whether he was ready to progress to a more strenuous level of work. Coronary-stricken subjects were carefully supervised during exercise by specially trained physical educators. In many subjects, the electrocardiogram was telemetered during the exercise sessions and usually showed significant displacement of the STT segment or arrhythmias (Figure 1). Adherence to the exercise plan was graded independently by the study physical educator who reviewed the attendance records but did not have knowledge of the heart rate, blood pressure or electro-

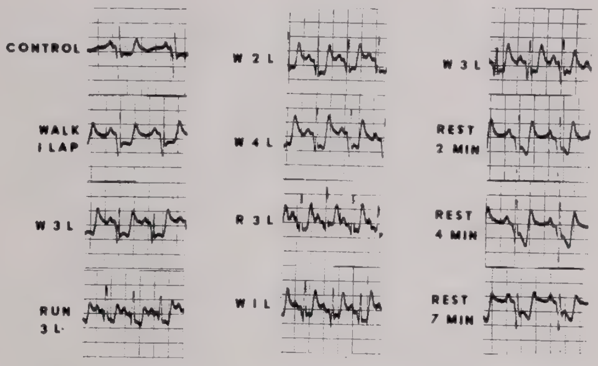

Fig. 1—Radio-transmitted electrocardiograms recorded during walking (W) and running (R) of a cardiac subject. Note that ST displacement decreases when the subject runs and recurs at rest. (L indicates 1/18 of a mile).

(Previously appeared in the following article:
Hellerstein, H. K. Exercise Therapy in Coronary Disease. New York Heart Association, Inc., Conference on Coronary Heart Disease: Preventive and Therapeutics Aspects. Reprinted from Bulletin of the New York Academy of Medicine Second Series 44:8, pp. 1028-1047, August, 1968).

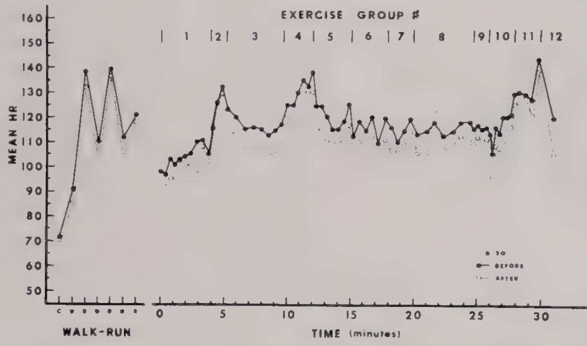

Fig. 2—Average heart rates of walk-run sequences (W = walk, R = run, C = control) and of consecutively performed calisthenics done routinely in the Case Western Reserve University Physical Conditioning Program.

The electrocardiograms of twenty subjects (average age 48 years) were telemetered before (solid lines) and several months after (dotted lines) participation in the program. Note that the average heart rate was almost 120 beats per minute, representing 70 per cent of their predicted maximal heart rate. Exercise numbers signify performance of the following exercises: (1) shoulder exercises, standing, warm-up; (2) hops, walk steps; (3) arm sweeps, standing; (4) hops, sailor's hornpipe; (5) body bends; (6) leg exercises, supine; (7) leg-arm-hip exercise, sitting on floor; (8) leg exercises, lying on side; (9) leg exercises, bicycle movements, supine; (10) sit-ups; (11) push-ups; and (12) shoulder exercises, standing, cool off.

cardiographic responses to bicycle ergometry. Grade 1 represented minimal or no participation, grade 2, 0.5 to 1.5; grade 3, 1.5 to 2.2; grade 4, 2.3 to 2.6; and grade 5, 2.7 or more (up to 5) hours per week of running and calisthenics.

In general, during calisthenics, the average heart rate was 120 beats per minute, which represent 70 per cent of the predicted maximal heart rate of subjects 45 to 50 years of age (Figure 2); during the run-walk sequences, heart rates of 145 to 150 were attained, approximating 85 per cent of maximal heart rate.

Results

The results of the active intervention program on a subgroup of 100 coronary-stricken and of 58 normal coronary-prone were analyzed in greater detail.[7] The average period of followup was 33 months. The average loss of body weight was approximately five pounds in both the coronary-stricken and the normal coronary-prone.

Serum Cholesterol

Serum cholesterol dropped significantly from an average of 263 to 242 mgm/dl, $p < .05$. Many subjects improved their physical fitness but did not reduce serum cholesterol unless they adhered to a fat-restricted diet. As noted previously, the serum cholesterol dropped significantly in the adherent group, $p < .001$, but not in the partial and non-adherents, $p < .2$.[1]

Physiologic Data

The physical fitness at the time of the initial evaluation was low compared to other populations[5] but similar in both the normal coronary-prone and coronary-stricken, i.e., 24.6 and 23.8 ml O_2/kg B.W./min., respectively. Physical fitness improved in a similar number of the normal coronary-prone (71 per cent) and of the coronary-stricken (64 per cent). The average oxygen uptake increased comparably (20

§ $\times 10^2$.

per cent—to 28.6 and 28.1 ml O_2/kg B.W./min., respectively) in both groups (Table).

Individual subjects showed noteworthy and exceptional improvements in performance. One 45-year-old executive with a posterolateral myocardial infarct regularly runs five to 10 miles several times a week, and is currently training for a well known marathon. He was telemetered during a five-mile run in 39 minutes, during which time he developed a heart rate up to 170 per minute without arrhythmias or ischemic manifestations.

The systolic blood pressure response to exercise was lower in the normal coronary-prone when compared to the coronary-stricken at the same work load.

In the improved fitness subjects, in addition to improvements of predicted maximal oxygen uptake and W.L. 150, decrements occurred for the same work level for the exercise heart rate, blood pressure, and heart rate times systolic blood pressure product, at highly significant levels, $p < .001$ (Table). The resting blood pressure decreased from 129.9/86.8 to 121.7/84.3 mm Hg., $p < .01$. In general, the improvement of exercise heart rate and blood pressure were concordant; however, approximately 20 per cent of the subjects whose heart rate response during exercise improved, failed to show an improvement of blood pressure.

Changes in Exercise Electrocardiogram Categories and Physical Fitness

Both the normal coronary-prone and coronary-stricken subjects showed an increased amplitude of the T waves as the heart rate decreased with training. Improvement in the exercise electrocardiogram was related to improvement in physical fitness. In the coronary-stricken the initial exercise electrocardiograms were abnormal or borderline in 49 per cent, normal in 48 per cent, and showed U-shaped ST segments in 3 per cent. The number of normal coronary-prone with initially abnormal exercise electrocardiograms (4 of 59) was too small to analyze for significant relationships. Eighty-four per cent of the coronary-stricken subjects with initial borderline or abnormal electrocardiogram who improved their exercise electrocardiogram also improved their physical fitness. *Seventy-nine per cent of coronary-stricken subjects who improved their physical fitness also showed improvement in their exercise electrocardiogram,* whereas only 31 per cent of coronary-stricken subjects who did not improve their physical fitness or who worsened it showed improvement in their exercise electrocardiogram ($p < .003$).[7] In the entire coronary-stricken group, irrespective of initial electrocardiogram category, electrocardiographic improvement occurred in 41 per cent of subjects in the improved fitness group, and in 14 per cent of those in the not improved or worsened physical fitness group, $p < .003$. Electrocardiographic deterioration occurred in 18 per cent of coronary-stricken subjects in the improved fitness group and in 44 per cent of those in the not improved or worsened physical fitness group, $p < .05$.

In coronary-stricken subjects with improvement of exercise electrocardiogram, the mean ST J displacement decreased from 1.74 ± 0.34 mm to 0.78 ± 0.16 mm, $p < .001$. The mean slope increased from 0.16 to ± 0.18 mv/sec to 0.91 ± 0.13 mv/sec, $p < .001$.

Similar percentages of coronary-stricken subjects improved their physical fitness whether the initial exercise electrocardiogram was normal, borderline, or abnormal. Physical fitness improved in 28 of 48 subjects (58 per cent) with initial normal exercise electrocardiogram, and in 33 of 49 subjects (67 per cent) with initial abnormal or borderline exercise electrocardiogram.

The normal coronary-prone failed to show significant changes in ST J displacement or ST segment slope to produce a change in electrocardiogram category.

Adherence to the Exercise Program

In general, the adherence to the training program was better than that reported by others. Sixty-eight per cent of the subjects adhered to a training program of two or more hours per week, for an average followup period of 33 months. Subjects with adherence Grades of 5, 4, and 3 showed similar degrees of improvement in physical fitness and similar low rates of deterioration.

Improvement in physical fitness was related to adherence to the exercise program. In the coronary-stricken, improvement in physical fitness occurred in 86 per cent (30 of 35), 69 per cent (9/13), 71 per cent (12/17), 27 per cent (3/11), and 35 per cent (6/17) of subjects with Grades 5, 4, 3, 2, and 1 adherence respectively. The difference in improvement between adherence grades 1 and 2 vs. the grades 3, 4, and 5 groups was significant, $p < .003$. Improvement in the exercise electrocardiogram was similarly related to adherence to the exercise program. Of the subjects with initial abnormal or borderline exercise electrocardiogram, improvement in the exercise electrocardiogram occurred in 64 per cent (9/14), 67 per cent (6/9), 75 per cent (9/12), 50 per cent (3/6), and 25 per cent (1/4) of subjects with Grades 5, 4, 3, 2, and 1 adherence respectively. Deterioration of physical fitness or of the exercise electrocardiogram of the coronary-stricken occurred more frequently in the low adherence groups.

The normals (normal coronary-prone) also demonstrated a similar tendency for improvement in physical fitness to be related to adherence to the exercise program, and for deterioration of the exercise electrocardiogram to be related to lack of adherence. However, these changes were not statistically significant.

Several subjects have failed to show improvement in their physical fitness, despite strict adherence to the training program. Coronary arteriograms have shown severe narrowing (75 to 90 percent) of two major vessels and 50 or more per cent narrowing of the third vessel. Apparently the limiting factor was a lack of significant source for collateral formation.

Cardiac catheterization studies on seven subjects before and after training have shown reduced heart rate, increased stroke volume and unchanged cardiac output after training.

Deaths

In the present study, the overall mortality rate was 2.1 per 100 coronary-stricken subject years. Of the 194 coronary-stricken subjects in the comparison group, the mortality rate was 3.5 per 100 subject years. In other studies (Feil), the death rate has been reported to be five or higher. [10]In the normal coronary-prone, the death rate was 5 per 1000 subject years, which is less than the expected mortality rate expected for men of this age group in the United States. However, the number of the normal coronary-prone group is small. No statement of significance is warranted because a true "control" population was in this feasibility study.

Discussion

This study demonstrates that an active intervention program of physical conditioning, including prescribed, supervised exercise, weight reduction and diet therapy is feasible and acceptable, and appears to be of benefit in the therapy of subjects with coronary heart disease (without congestive heart failure).

The major determinants of successful physical reconditioning include a comprehensive approach, adequate and enthusiastic staffing, motivation of the study subjects and substantial adherence, systematic and repeated evaluation and counselling, and viable myocardium and adequate arterial sources to enhance the coronary circulation.

The beneficial mechanisms of physical conditioning have not been clearly elucidated. The similarity of the improvement in circulatory functions in the coronary-stricken and normal coronary-prone implies similar adaptation of the heart, of the periphery (skeletal musculature), and of the nervous system (baroreceptors, reflexes, etc.). Several studies have demonstrated improvement in the coronary arterial circulation in the dog and rat.[11,12] Although one of our subjects showed increased coronary collaterals after conditioning,[1] we have been impressed by the fact that marked improvement of aerobic capacity has occurred in some of our subjects whose post-training coronary arteriograms have shown no evidence of grossly visible collateralization. There has been no evidence of reversal or coronary atherosclerosis in our subjects. Whether the reduction of serum cholesterol and of triglycerides (in other studies) has retarded the atherosclerotic process is unproved. The psychologic changes are striking, with lessening of depression,[1] and improvement of self-image, insight and marital relations.[13] Many of the coronary-stricken subjects have indicated that they conceive of themselves as being less disabled after physical conditioning. Claims have been made that they "think" and even hear better!

The reduction of the heart rate and blood pressure and of myocardial oxygen needs at rest and during effort, and the improvement of stroke volume, dp/dt, and mood suggest a change in catecholamine metabolism turnover or storage, possibly in both the sympathetic nervous system (in the heart) and the central nervous system. Other studies have shown that coronary-stricken subjects release greater amounts of catecholamines after effort or emotional stresses. The higher-exercise heart rate and blood pressure of our subjects confirm this finding. In addition, Schildkraut and Kety have indicated that the biogenic amines of the brain are reduced in depressed states.[14] The present study suggests the possibility that there is an interrelationship between the psychologic and circulatory changes after physical conditioning. However, the nature of this relationship—coincidental or correlative—has not been clarified and remains conjectural at this time.

Unsolved Problems

Before large scale programs of physical conditioning are undertaken, more information is needed in regard to: selection of subjects, criteria for exclusion, scientific bases for exercise prescription and proscription, time of onset of program, duration and frequency of exercise for optimal effects, endpoints to stop exercise, monitoring devices, enhancement of motivation and adherence, and evaluation techniques. My associates and I have been impressed by the hazards encountered by subjects who ill-advisedly have joined in an unsupervised jogging program, without preliminary medical evaluation. Mass prescription of exercise for middle-aged subjects, many of whom have silent coronary artery disease, is justified only if techniques and facilities are made available for comprehensive cardiovascular evaluation, including multilevel exercise testing and electrocardiographic recording.

Summary

The present study of 402 normal coronary-prone subjects and of 254 coronary-stricken subjects demonstrates that a supervised program of physical conditioning improved both the physical fitness and the exercise electrocardiograms of coronary-stricken subjects and tended to prevent the deterioration of the exercise electrocardiogram in normals. Improvement in both physical fitness and the exercise electrocardiogram was a direct function of adherence to the program. Although the present report deals with an uncontrolled feasibility study, it would appear that an active conditioning program can be used safely in the treatment of selected coronary-stricken subjects without congestive failure, and in the reconditioning of normal coronary-prone men.

Reducing Cardiovascular Risk*

The Basis and Feasibility

JEREMIAH STAMLER, M.D.†
Chicago, Illinois

I THINK WE CAN best distill what we have learned here by posing a series of questions and answers.

Is a Preventive Effort Needed?

The answer is "yes." The nature of the adult cardiovascular problem today in our country and in other economically well-developed countries is such that without a preventive effort we cannot achieve a decline in these diseases. This is based on the data on sudden death, mortality with the acute coronary event, prognosis after the acute event, and estimates of the potential of coronary care units.

How Adequate Is Our Preventive Effort

Based on Dr. Wilber's data it is obvious that not more than 10 per cent of the total number of hypertensives in our population are under adequate care. The figure is similar for diabetes in our communities and worse for hyperlipidemia. If we look at the data of the Coronary Drug Project, we see that approximately 50 per cent of this large group of coronary cases are still smoking cigarettes and about as many are overweight. Therefore I do not think that at the present time the long-term preventive effort, either primary or secondary, is adequate. There is a need for a preventive effort in terms not only of the nature of the problem but also of the adequacies of the current effort.

The overwhelming bulk of our medical practitioners today, generalists and internists, the army who must contend with this problem, are preoccupied with the care of people who are ill; and when we talk about a primary preventive effort, we are talking about an additional load of long-term medical care. All of the people in the practice of medicine admit they are involved very little in this kind of effort. No one believes that the current effort is adequate except for those who find the idea of a preventive effort absurd.

---

†Executive Director, Chicago Health Research Foundation.

Is a Preventive Effort Justified?

It is true that field trials are needed to prove unequivocally that interference with cigarette-smoking habits, elevated blood pressure, and elevated serum lipid level will, indeed, alter the natural history of this disease. Despite the overwhelming and consistent mass of evidence on risk factors, as long as these final proofs from definitive mass field trials are not available, one cannot make categorical statements, based on present knowledge, that preventive programs are justified. One has to make a qualified statement, and I think that the position taken by the American Heart Association, by the Council on Food and Nutrition of the American Medical Association, by the Second National Conference on Cardiovascular Diseases and by the President's Commission on Heart Disease, Cancer and Stroke is very sound: namely, that the great bulk of evidence indicates the possibility of prevention. Hence it seems wise to proceed, in view of the scope of the problem and the need for primary prevention, and the fact that much of the preventive effort is nutritional and hygienic and therefore relatively safe, with drugs secondary and adjuvant. There is no indication that the trend of coronary disease will decline without such endeavors. My answer to the question is: Yes, prevention is justified, based on present knowledge and for the reasons that there is great evidence for the possibility of prevention and that the measures to attempt realization of that possibility are highly safe. I would add, however, that we need to proceed to get the field trials finished so that we can answer the questions more definitively.

Physicians, internists, cardiologists and local heart associations have a deep stake in the advances achieved by field studies such as the Coronary Drug Project. As a result of these studies definite guidance in treatment is obtainable, and it is therefore in their own interest to cooperate as fully as they can. Take also the example of the Cooperative Veterans Administration Study on therapy of moderate hypertension. Prior to its positive result, some physicians maintained that treating moderate hypertension was ineffectual and might even do harm: a valid position until the Veterans Administration Study. The small clinical studies on 20 to 30 patients a year, showing that drugs lower blood pressure or lipids, tell us nothing about the long-term effect of toxicity, survival, or reduced attacks. I think the entire community should be delighted in the laborious studies supported by the National Heart Institute and the Veterans Administration, and by the patience and cooperation of the medical profession and participants.

What Should Be the Main Thrust and Strategy of the Preventive Effort?

The thrust of the main effort for prevention must be treatment *before* illness. A second but very important thrust is the effective, long-term care of those who have been acutely ill but have recovered. I am grateful that my relatively short life in medicine has given me the opportunity to know Paul White and appreciate his lesson on the importance of long-term follow-up and care.

We have to formulate a strategy and fight for it. We are dealing with a disease that has a mortality rate of 600,000 per year, 165,000 under age 65. It is a war which will never be won without a strategy which is explicit, formulated and fought for in order, among other things, to get the resources which are needed. It is very easy for the public to be misled as to the central strategy in dealing with the heart problem. And if the public is misled, then it will also become confused and money will be wasted on causes which are not really justified or are secondary to the preventive effort needed. These issues have to be debated in public, decisions reached, and policy-making bodies influenced.

The second element of strategy is the maintenance and fostering of a social approach to the problem. The history of medicine teaches us that epidemic disease is never solved exclusively by an approach between the individual physician and his patient, as important a contribution as that is. TB was not solved that way, nor pellagra nor scurvy nor rickets, typhoid, polio, etc. The mechanisms of society as a whole have to be intermeshed with the approach of the individual and his physician. In our country, traditionally, the social approaches have always been two-pronged when they have been successful. On the one hand they have been governmental—federal, state and local—and on the other hand, voluntary. We now find this epitomized in the approach of the American Heart Association and the Regional Medical Program which is federally financed but emphasizes local initiative, coordination and cooperative planning.

The third and final element of strategy takes into account the special aspects of our adult population. Millions of Americans do not present themselves to physicians from one year's end to the next. There are millions of people who are walking around nurturing their coronary risk factors, prior to developing an acute and all too often fatal event. I know of no way to cope with this problem except through the systematic development of mass detection efforts of a public health nature, through non-M.D. personnel: primarily, technicians, nurses, especially trained nurses' aides and technician-aides, and others who will go among the population as we have been doing in Chicago, find what is wrong with them and bring them into the physicians for long-term care.

What Are the Elements of a Preventive Program?

Diet is of great importance, since it influences at least four of the risk factors that concern us. It influences all aspects of hyperlipidemia; it is related to obesity, and also to the risk of hyperglycemia and hypertension. There are many middle-aged hypertensives and diabetics who will be corrected by an effective diet alone.

The American Heart Association Diet as recommended for the last several years is a good foundation, moderate in calories to correct overweight and keep it corrected, moderate in total fat (30-35 per cent of calories), low in saturated fat and low in cholesterol and moderate in salt, at the 5 gm. level where there is a reason to control salt intake. The American Heart Association diet is a good diet for managing almost all types of hyperlipidemia; it is fine for obese adults, hypertensives, diabetics and their families.

In addition to diet the more effective control of cigarette smoking is essential. Cigarette smoking rates are highest today in men and women under 40. This means that a good number of middle-aged men have discontinued smoking, so that however vast the problem, there is a possibility of making progress against it with skill, persistence, sound public policy and a long-term approach.

Further, I think those of us who have been preoccupied with the lipid question have tended to forget the importance of hypertension in all areas and conditions of life. Hypertension can be controlled in a great majority of patients with modern drugs, and this control can be sustained. It does influence prognosis. We must emphasize hypertension much more as a risk factor and therefore its earliest possible detection and its effective long-term management. It is a sad situation when large numbers of people do not remain under long-term management because they are not given to understand the need to do so. The economic problem can be solved by dollars; the confusion problem is more difficult. It depends first and foremost on the physician. About exercise, I think there should be a rational and cautious approach until more knowledge is acquired.

What Is the Role of Pharmacology?

If industrial civilization with its rich diet, its sedentary living, its smoking, and its tensions has given us epidemic coronary disease, then I cannot believe that drugs are main answers. That is why I emphasize what might be called the nutritional, hygienic and social approach, and relegate pills to a contributory role based on the specific needs of individual patients.

Is Such a Preventive Effort Possible?

Given adoption of a correct strategy, a key step is detection effort to find the people at highest risk. We have the scientific and technological means to do this. The second element is the long-term sound effort to change habits and thus correct risk factors.

From our experience with the Diet-Heart Study and from experiences in Scandinavia, Britain, Chicago and New York, we know that large numbers of adults are prepared to participate in such efforts and that in a sizable proportion of them sustained participation will be reflected in such simple measurements as weight, serum cholesterol, blood pressure and even smoking patterns. Thus the challenge faces us, and the public is willing.

What Are Reasonable Perspectives for the Coming Years?

We are tackling a problem as tough in its social roots and its vastness as the tuberculosis problem was. To build on a firm foundation, and to build steadily, we must step-by-step diminish the smoking prevalance rate in middle-aged men, 10 per cent per year, increase the number of well-managed hypertensives by 10 per cent per year, etc. Despite sloth and gluttony, I am convinced that we will have no trouble in winning, granted some remnants of sanity still prevail in the world.

When the Brain Sleeps

The water hemlock, also known by its Latin name of *Cicuta virosa*, has its place in legends as the poison that cut short the life of Socrates, the famed ancient philosopher, who was made to take his own life while in prison.

The water hemlock occurs in the Soviet Union. It is widespread in the Urals, the Far East, the Karelo-Finnish S.S.R. and, to a lesser degree, in the Moscow region. Its root looks much like the root of parsley, and is often mistaken for it, and eaten. The result of such a mistake is fatal.

Doctor Ror works at a polyclinic in Verkhnaya Tavda, a Urals town. The water hemlock is often met in its neighborhood, and victims of the murderous plant are quite frequent there.

In such cases Doctor Ror, like any other doctor would in her place, did everything in her power to save the life of her patient. She injected camphor and caffeine to stimulate the heart and respiration, she applied artificial respiration, administered tannin, and did everything else that could bring some degree of relief. But medicine is helpless against the Cicuta poison. And whenever a patient came to the casualty ward whose body was in convulsions, who foamed at the mouth, whose face was blue, who was unconscious and whose pulse was so weak that it could scarcely be felt, and whose breath was nothing more than a death-rattle, it was clear to the physician that his case was hopeless.

A patient was brought to Doctor Ror on July 7, 1947. He had eaten water hemlock. His respiration was weak, there was foam at his mouth and he had cramps at five-minute intervals. In half an hour, an hour at most, he would be a corpse.

But in six hours the patient was out of danger, and in another three days he was discharged. In six weeks, when Doctor Ror saw her patient again, she could scarcely believe that this strong-looking chap, who was the picture of health, had only recently been at death's door.

Doctor Ror had read of Professor Galkin's* studies a few days before the hemlock victim was brought to her. She did not hesitate, therefore, to apply anesthesia. There was nothing to lose anyway: Life was fast ebbing in her patient.

The ether anesthesia lasted six hours with brief intervals. When Doctor Ror decided that the poison had been expelled from the organisms, she terminated it.

In July, August, and September 1947 three more Cicuta victims were saved in a similar way.†

---

* Professor Galkin, a Leningrad patho-physiologist, discovered an amazing phenomenon: Many properties of the organism undergo great changes under the effects of narcotic sleep. Anesthetized cells can live under conditions that would be fatal to them under ordinary circumstances.

new FLUOGEN™ (influenza virus vaccine, bivalent) immunizing antigen, ether extracted

"Purified" flu vaccine is tidy and homogeneous...but that's just the starting material for FLUOGEN.

First, we ether-extract our viruses—stripping away a lot of reaction-causing lipids and egg protein in the process.

Then we scrub off more troublemakers with our exclusive gel filtration process.

Result: An ultrapure antigen, with the adult dose reduced to 0.5 cc. With this dose, antibody levels are equal or superior to those provided by our conventional influenza virus vaccines but FLUOGEN is **only slightly more than half as likely to cause side effects.***

Description: FLUOGEN (Influenza Virus Vaccine, Bivalent, Ether Extracted Antigen) (Types A_2 and B) is composed of the antigen of the strains of influenza viruses recommended by the Division of Biologics Standards, National Institutes of Health, Public Health Service. It is formulated to contain 400 CCA (chick cell agglutination) units of extracted immunizing antigen of type A_2/Aichi/2/68 strain (Hong Kong variant) and 300 CCA units of extracted immunizing antigen of B/Massachusetts/3/66 strain for a total of not less than 700 CCA units per each 0.5 cc. dose. **Method of Preparation:** The influenza viruses are propagated on developing chick embryos. The extra-embryonic fluid containing the virus suspension is harvested, clarified by filtration and concentrated and refined by ultracentrifugation. Polysorbate-80, U.S.P. (175 mcg. per 0.5 cc.) is added to the refined concentrate. The refined concentrate is extracted with ethyl ether, stabilized with formalin, and preserved with 0.01% thimerosal (mercury derivative). The vaccine contains not more than 1:12,000 formalin, used during the process. It does not contain penicillin. Aluminum phosphate, 1.5 mg. per 0.5 ml. is added to the vaccine as an adjuvant. **Indications:** FLUOGEN is indicated for the production of immunity to influenza produced by the strains of virus containing antigens related to those in the vaccine. FLUOGEN is recommended primarily as a seasonal booster for persons who were previously vaccinated with vaccines containing the A_2 Hong Kong variant. It may also be used for primary immunization of those who have not previously received the Hong Kong variant. It is recommended that both primary and booster immunization be completed by early December since influenza is more likely to appear during cold weather. It is understood that should epidemic conditions be predicted, immunization procedures should be initiated regardless of the time of year. Attempts to produce immunity following the appearance of an epidemic may be less successful because of the rapidity with which the disease spreads and the time required for antibody production following vaccination. The degree of protection afforded by immunization with any vaccine may not be sufficient to prevent the disease if the exposure to the influenza virus strains is overwhelming or if the virus strains are not closely related antigenically to those used in the production of vaccine. Although routine vaccination of healthy groups of adults and children is not recommended, when widespread epidemics of influenza are forecast, vaccination may be considered if above-average levels of absenteeism would disrupt satisfactory operations in industries, schools, and other such groups. **Contraindications:** The use of products prepared from the embryonic fluid of chicken eggs is contraindicated in persons with a history of allergy to eggs, chicken, chicken feathers, or chicken dander. In persons suspected of having an allergic condition, immunization procedures should be preceded by a scratch test or an intradermal injection (0.05 ml. to 0.1 ml.) of vaccine diluted 1:100 in sterile saline to determine possible sensitivity to the minute residual egg protein that may be present in the vaccine. A positive skin reaction contraindicates immunization with the vaccine. Immunization should be deferred in the presence of any acute respiratory disease or other active infection. It should also be deferred in the presence of an epidemic of poliomyelitis unless the risk of influenza represents a greater threat to the patient than the increased possibility of poliomyelitis. **Precautions:** A separate sterile syringe and needle should be used for each patient to prevent transmission of homologous serum hepatitis virus or other infectious agent from one person to another. Reusable glass syringes and needles should be heat sterilized. Epinephrine should be immediately available for use should an acute anaphylactoid reaction occur in individuals having an undisclosed hypersensitivity to any component of the vaccine. Because of the possibility of a febrile reaction following immunization with influenza virus vaccine, the wisdom of attempting to immunize patients with a history of febrile convulsion should be given careful consideration. **Adverse reactions:** Most frequent reaction reported in early clinical studies[†] with ether-extracted vaccine was tenderness at the site of injection. Headache and malaise were reported in up to about 12% of subjects. Nausea and fever occurred in approximately 5% of the patients. Muscle ache, joint pain, chills, fatigue, and anorexia occurred in less than 5% of the subjects. **Package information:** Bio 579—5 cc. rubber-diaphragm-capped vial. Each 5 cc. vial contains sufficient vaccine to deliver ten 0.5 cc. doses.

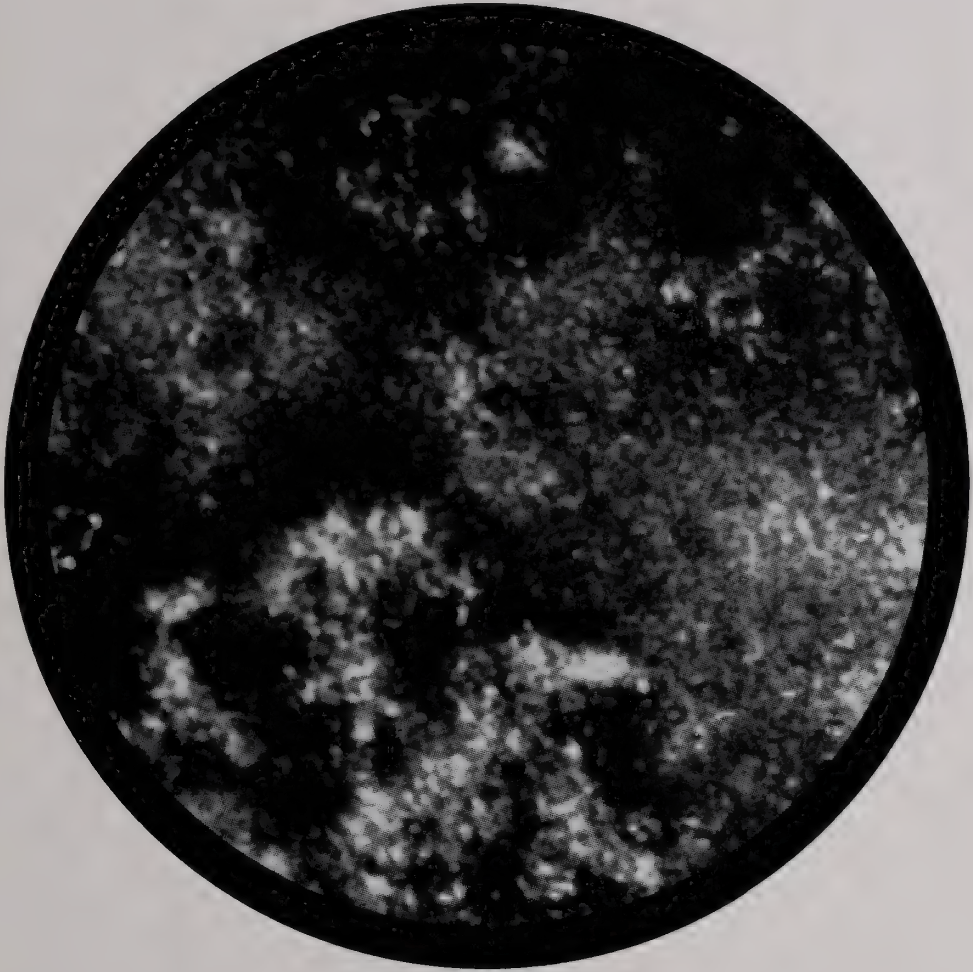
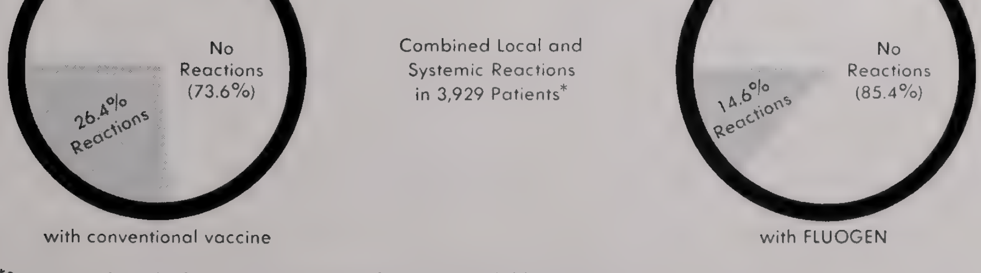
PARKE-DAVIS

we had to take our conventional flu vaccine two steps beyond "purified" to make it look like this...



...and cut its side effects almost in half



*Summary of results from three studies. References available on request.

Convalescing . . . but still a long way to go. Anxiety can make it even longer.

Convalescence following medical or surgical procedures may be almost endless to an anxious patient. And, indeed, anxiety with some patients actually retards progress—for example, by inducing insomnia and reducing cooperation.

As physicians have found during nearly 15 years of widespread use, Equanil may be a beneficial part of aftercare. It helps relieve anxiety and tension, thus often aiding your primary therapy.

Indications: For use in management of anxiety and tension occurring alone or as accompanying symptom complex to medical and surgical disorders and procedures. Though not a hypnotic, fosters normal sleep through antianxiety and related muscle-relaxant properties.

Contraindications: History of sensitivity to meprobamate.

Important Precautions: Carefully supervise dose and amounts prescribed, especially for patients prone to overdose themselves. Excessive prolonged use has been reported to result in dependence or habituation in susceptible persons, as alcoholics, ex-addicts, and other severe psychoneurotics. After prolonged excessive dosage, reduce dosage gradually to avoid possibly severe withdrawal reactions. Abrupt discontinuance of excessive doses has sometimes resulted in epileptiform seizures.

Warn patients of possible reduced alcohol tolerance, with resultant slowing of reaction time and impairment of judgment and coordination.

Reduce dose if drowsiness, ataxia or visual disturbance occurs; if persistent, patients should not operate vehicles or dangerous machinery.

Side Effects include drowsiness, usually transient; if persistent and associated with ataxia, usually responds to dose reduction; occasionally concomitant CNS stimulants (amphetamine, mephentermine sulfate) are desirable. Allergic or idiosyncratic reactions are rare, but such reactions, sometimes severe, can develop in patients receiving only 1 to 4 doses who have had no previous contact with meprobamate. Previous history of allergy may or may not be related to incidence of reactions. Mild reactions are characterized by itchy urticarial or erythematous maculopapular rash, generalized or confined to groin. Acute nonthrombocytopenic purpura with cutaneous petechiae, ecchymoses, peripheral edema and fever have been reported. One fatal case of bullous dermatitis following intermittent use of meprobamate with prednisolone has been reported. If allergic reaction occurs, meprobamate should be stopped and not reinstituted. Severe reactions, observed very rarely, include angioneurotic edema, bronchial spasms, fever, fainting spells, hypotensive crises (1 fatal case), anaphylaxis, stomatitis and proctitis (1 case) and hyperthermia. Treat symptomatically as with epinephrine, antihistamine and possibly hydrocortisone. Aplastic anemia (1 fatal case), thrombocytopenic purpura, agranulocytosis and hemolytic anemia have occurred rarely, almost always in presence of known toxic agents. A few cases of leukopenia, usually transient, have been reported on continuous administration.

Meprobamate may sometimes precipitate grand mal attacks in patients susceptible to both grand and petit mal. Extremely large doses can produce rhythmic fast activity in the cortical pattern. Impairment of accommodation and visual acuity has been reported rarely. After excessive dosage for weeks or months, withdraw gradually (1 or 2 weeks) to avoid recurrence of pretreatment symptoms (insomnia, severe anxiety, anorexia). Abrupt discontinuance of excessive doses has sometimes resulted in vomiting, ataxia, tremors, muscle twitching and epileptiform seizures. Prescribe very cautiously and in small amounts for patients with suicidal tendencies. Suicidal attempts have resulted in coma, shock, vasomotor and respiratory collapse and anuria. Excessive doses have resulted in prompt sleep; reduction of blood pressure, pulse and respiratory rates to basal levels; and occasionally hyperventilation. Treat with immediate gastric lavage and appropriate symptomatic therapy. (CNS stimulants and pressor amines as indicated.) Doses above 2400 mg./day are not recommended.

Composition: Tablets, 200 mg. and 400 mg. meprobamate. Coated Tablets, WYSEALS® EQUANIL (meprobamate) 400 mg. (All tablets also available in REDIPAK® [strip pack], Wyeth.) Continuous-Release Capsules, EQUANIL L-A (meprobamate) 400 mg.

EQUANIL®
(meprobamate)

Wyeth®

Wyeth Laboratories Philadelphia, Pa.

Photo professionally posed.

For elderly patients in need of a mild tranquilizer consider **Tybatran**®
brand of tybamate

(When you consult
the Prescribing Information
you may agree
it makes good sense)

PRESCRIBING INFORMATION

Indications: Tybatran (tybamate) has afforded symptomatic improvement in a variety of psychoneurotic disorders, especially in the treatment of the anxiety and tension components of psychoneuroses. Anxiety states manifested somatically have responded to Tybatran (tybamate).

Tybatran (tybamate) has been useful in the control of agitation in the aged and in the alleviation of some of the adverse emotional accompaniments of senility.

Tybatran (tybamate) has been used with benefit in the treatment of depressive symptoms associated with anxiety and other symptoms of psychoneuroses. However, it is not indicated for primary treatment of depressive states. It is not an antipsychotic agent, although it has been used as adjunctive therapy in some psychotic patients.

Dosage: One 350 mg. capsule, 3 times daily and two at bedtime is suggested as the adult starting dose. Adjust to suit individual requirements. Daily doses above 3000 mg. are not recommended.

Contraindications: Known hypersensitivity to tybamate. Since no studies have been done with this drug in human pregnancy, it should not be used in pregnancy unless the potential benefit outweighs the risk.

Warnings: Administer cautiously to patients receiving phenothiazines or other CNS depressants or having history of convulsive seizures (See Adverse Reactions). Consider possibility of additive actions with alcohol or other psychotropic agents, particularly phenothiazines or MAO inhibitors.

Precautions: Avoid abrupt withdrawal after prolonged use, although withdrawal symptoms have not been reported to date. Exercise caution in addiction-prone individuals. If symptoms of hypersensitivity occur, discontinue at once and initiate appropriate symptomatic treatment. Avoid activities requiring optimal mental alertness if drowsiness or vertigo are present. As with any new drug, use cautiously in patients with history of drug allergies, blood dyscrasias, and hepatic or renal disease; periodic measurements of hepatic, hematopoietic and renal function should accompany prolonged and/or high doses.

Adverse Reactions: Most frequent reactions, rarely requiring discontinuation of tybamate, include drowsiness, dizziness, nausea, insomnia, and euphoria. There have been a few reports of skin rash, urticaria, and pruritus. Rare side effects include hyperactivity, fidgetiness, flushing, and tachycardia, suggesting excessive stimulation; also ataxia, unsteadiness, confusion, feeling of unreality, "panic reaction," fatigue, headache, paresthesias, vertigo, gastrointestinal disturbances, glossitis, and dry mouth. Grand mal or petit mal seizures have been reported in a few hospitalized psychotic patients receiving tybamate (up to 6000 mg. daily) together with phenothiazines and other psychotropic agents, but not with tybamate alone. Consider the possibility of rare, serious adverse reactions such as may occur with the related drug, meprobamate. If excessive amounts are ingested, gastric lavage and symptomatic therapy, including central stimulants as necessary, are recommended. Before prescribing, consult package circular.

Supply: Tybatran (tybamate) is available in green, sealed capsules of three strengths: 350 mg., 250 mg., and 125 mg. Each strength is supplied in bottles of 100 and 500.

Steven Strong, M.D.

SEPTEMBER, 1969

Special Issue
Chronic Respiratory Diseases in Children and Adolescents

Dear Doctor,
You made me
what I am today–
a whole lot
slimmer!

TEPANIL—the right start in support of the weight-control program *you* recommend. It reduces the appetite. Doesn't kill it. Weight loss is significant—gradual—yet there is a relatively low incidence of CNS stimulation. Because TEPANIL works on the appetite, not on the "nerves."

Contraindications: Concurrently with MAO inhibitors, in patients hypersensitive to this drug; in emotionally unstable patients susceptible to drug abuse.

Warning: Although generally safer than the amphetamines, use with great caution in patients with severe hypertension or severe cardiovascular disease. Do not use during first trimester of pregnancy unless potential benefits outweigh potential risks.

Adverse Reactions: Rarely severe enough to require discontinuation of therapy, unpleasant symptoms with diethylpropion hydrochloride have been reported to occur in relatively low incidence.

As is characteristic of sympathomimetic agents, it may occasionally cause *CNS effects* such as insomnia, nervousness, dizziness, anxiety, and jitteriness. In contrast, CNS depression has been reported. In a few epileptics an increase in convulsive episodes has been reported.

Sympathomimetic *cardiovascular effects* reported include ones such as tachycardia, precordial pain, arrhythmia, palpitation, and increased blood pressure. One published report described T-wave changes in the ECG of a healthy young male after ingestion of diethylpropion hydrochloride; this was an isolated experience, which has not been reported by others.

Allergic phenomena reported include such conditions as rash, urticaria, ecchymosis, and erythema.

Gastrointestinal effects such as diarrhea, constipation, nausea, vomiting, and abdominal discomfort have been reported.

Specific reports on the hematopoietic system include two each of bone marrow depression, agranulocytosis, and leukopenia.

A variety of miscellaneous adverse reactions have been reported by physicians. These include complaints such as dry mouth, headache, dyspnea, menstrual upset, hair loss, muscle pain, decreased libido, dysuria, and polyuria.

Convenience of two dosage forms: TEPANIL Ten-tab tablets: One 75 mg. tablet daily, swallowed whole, in midmorning (10 a.m.); TEPANIL: One 25 mg. tablet three times daily, one hour before meals. If desired, an additional tablet may be given in midevening to overcome night hunger. Use in children under 12 years of age is not recommended.

DECLOSTATIN® 300 b.i.d.

Demethylchlortetracycline HCl 300 mg
and Nystatin 500,000 units
CAPSULE-SHAPED TABLETS Lederle

To guard susceptible patients against intestinal monilial overgrowth during broad-spectrum therapy—the protection of nystatin is combined with demethylchlortetracycline in DECLOSTATIN.

For your susceptible candidates, prescribe DECLOSTATIN—the broad-spectrum therapy that prevents monilial overgrowth.

Contraindication: History of hypersensitivity to demethylchlortetracycline or nystatin.

Warning: In renal impairment, usual doses may lead to excessive accumulation and liver toxicity. Under such conditions, lower than usual doses are indicated, and, if therapy is prolonged, serum level determinations may be advisable. A photodynamic reaction to natural or artificial sunlight has been observed. Small amounts of drug and short exposure may produce an exaggerated sunburn reaction which may range from erythema to severe skin manifestations. In a smaller proportion, photoallergic reactions have been reported. Patients should avoid direct exposure to sunlight and discontinue drug at the first evidence of skin discomfort. Necessary subsequent courses of treatment with tetracyclines should be carefully observed.

Precautions: Overgrowth of nonsusceptible organisms may occur. Constant observation is essential. If new infections appear, appropri
measures should be taken.

In infants, increased intracranial pressure with bulging fontanels
been observed. All signs and symptoms have disappeared rapidly u
cessation of treatment.

Side Effects: Gastrointestinal system—anorexia, nausea, vomiting, di
rhea, stomatitis, glossitis, enterocolitis, pruritus ani. Skin—maculop
ular and erythematous rashes; a rare case of exfoliative dermatitis
been reported. Photosensitivity; onycholysis and discoloration of
nails (rare). Kidney—rise in BUN, apparently dose related. Transi
increase in urinary output, sometimes accompanied by thirst (rar
Hypersensitivity reactions—urticaria, angioneurotic edema, anaphyla

Dulcolax®...so predictable you can almost set patients by it

Dulcolax works so effectively that the time of bowel evacuation can often be predicted.

Dulcolax tablets taken at night will usually result in a convenient bowel movement the following morning. Dulcolax suppositories generally work within 15 minutes to an hour.

Dulcolax may be given to the aged, pregnant or nursing women, and children. It may be particularly helpful in conditions in which straining should be avoided. The drug, however, is contraindicated in the acute surgical abdomen.

Dulcolax® bisacodyl

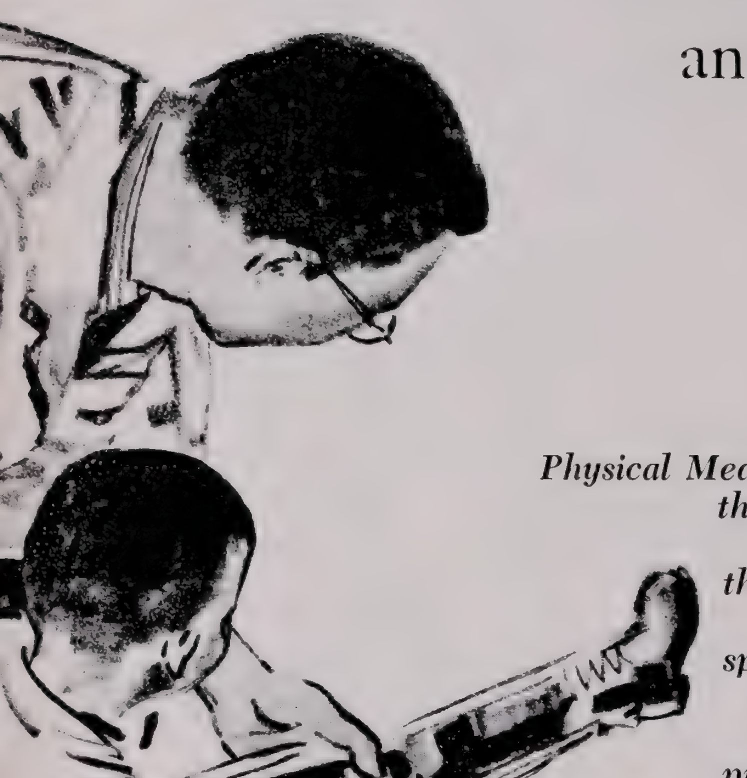
Fellowships

in PHYSICAL MEDICINE and REHABILITATION

UNIVERSITY OF MINNESOTA
SCHOOL OF MEDICINE
Minneapolis, Minnesota



Physical Medicine and Rehabilitation includes physical therapy, occupational therapy, rehabilitation counseling, guidance, and training of the physically handicapped, and is one of the most rapidly expanding and rewarding specialties in medicine. Trained physiatrists are insufficient in number and are in great demand in medical schools, private practice, Veterans Administration Hospitals, and many governmental institutions for the disabled. Physical Medicine offers unusual opportunities for the young physician seeking specialization.

The three-year residency program, beginning at any time, i approved by the American Board of Physical Medicin and Rehabilitation. The program may lead to a M.S. degree i physical medicine if desired. One year's credit in th residency is given for a year of training in another approve specialty or for four years of general practice experienc Ph.D. degrees are also offered for those planning a career i academic medicine. Extensive research facilities are availab to interested residents and as part of programs leadin to advanced degrees

Salary is dependent on qualifications. Tax sheltered stipends ar available in salary ranges from $6,000 to $11,000, plus $50 for each dependent. We will pay for visits in selected cases. Call o write for further information

Chairman's Letter

Chronic Respiratory Disease in Children

THE EXTENT TO which chronic respiratory diseases cripple children was reported in three recent United States surveys. The first, July '59-61, concluded that one of every ten children was handicapped by asthma, bronchitis, bronchiectasis, cystic fibrosis, emphysema, or congenital pulmonary disorders. These conditions caused almost half of all childhood chronic diseases.

The second survey, July '61-63, found that over 50 percent of persons handicapped by respiratory diseases were confined to bed for one or more days, 11 percent for more than thirty days.

The third survey, July '63-65, showed that these chronic respiratory conditions caused 13 percent of all disability under age 45.

Furthermore, these diseases caused 10 percent of the deaths in persons under 20 years of age (Vital Statistics U.S., 1966).

The apparent mildness of the early symptoms of pathology in these diseases, i.e., cough or tachypnea (Waring and Harries)* are often slighted by patients, parents, and physicians who thereby miss the opportunity for preventive treatment (Waring).*

Even, if the symptoms are appreciated, the need for special treatments and for long-term frequent observations in order to control or prevent progression of the disease (Matthews and Doershuk)* is frequently not appreciated.

The long-term work in this field by the National Cystic Fibrosis Research Foundation has recently encouraged the Congress to fund Pediatric Pulmonary Centers under two Federal Programs (Herndon).*

The combination of voluntary health agencies and the Federal Government should do much to solve the problems of inadequate facilities and funds (1) for care of children with these diseases (2) for research into their pathogenesis and (3) for educational programs for physicians and paramedical personnel.

The treatment techniques which have improved the prognosis for cystic fibrosis (Pogue and Warwick)* have been shown to be similarly effective for many children with other chronic respiratory problems. While specific therapy for all these diseases will depend upon discovery of the basic abnormalities, clinical and basic studies of the mechanisms of and recovery from lung damage, of susceptibility and resistance to infections, and of pulmonary function in health and disease will make it possible to slow down, control, or even reverse pulmonary damage in these diseases.

The magnitude of the chronic respiratory disease problem in children and adolescents (Kendig)* emphasizes the need for expansion of effort, manpower, training and research into diagnosis, care, and prevention and the smallness of the resources available to expand manpower, training, and research.

Funds have been available to exert a direct influence on cystic fibrosis. That effort ought to be considered a pilot study on a severe chronic pediatric pulmonary disease, and an example of how to proceed on the greater problems.

Chronic Respiratory Diseases in Children*

EDWIN L. KENDIG, JR., M.D.†
Richmond, Virginia

THE STUDY of the unglamorous chronic respiratory disease in children has lagged behind that in other pediatric subspecialties during recent years. Endocrinology, cardiology, the study of inborn errors of metabolism and developmental problems have all at one time or another been the glamour field for pediatricians.

There has, however, been a great change in the past 30 years. In 1938 cystic fibrosis was considered a rare pancreatic disorder, uniformly fatal and affecting only a small number of infants; no specific antimicrobial agents were available for the treatment of tuberculosis; and the unclassified mycobacteria were thought to be harmless saprophytes. Sarcoidosis was a rare disease indeed and histoplasmosis was considered a systemic fungous disease which was uniformly fatal. Bronchogenic carcinoma was not a major problem and cigarette smoking as a cause had not been suspected. Pulmonary function in children was a field barely touched.

A partial listing of chronic respiratory diseases and problem areas of the present day might be catalogued as follows:

(1) Hyaline Membrane Disease; (2) Bronchial Asthma; (3) Cystic Fibrosis; (4) Atelectasis; (5) Bronchiectasis; (6) Tuberculosis; (7) Systemic Mycoses; (8) Infection with the Unclassified Mycobacteria; (9) Sarcoidosis; (10) Familial Dysautonomia; (11) Histiocytosis X; (12) Collagen Diseases; (13) Visceral Larva Migrans; (14) Loeffler's Syndrome; (15) Psittacosis; (16) Hemosiderosis; (17) Idiopathic Diffuse Interstitial Fibrosis (Hamman-Rich); (18) Pulmonary Alveolar Proteinosis; (19) Alveolar Microlithiasis; (20) Bronchogenic Carcinoma; (21) Chronic Granulomatosis.

Hyaline Membrane Disease

Hyaline membrane disease, the respiratory distress syndrome usually occurring in premature infants, was first described more than 60 years ago. However, it is only in the past 15 years that the subject has attracted such great interest and, while much knowledge has been gained, there is still no completely endorsed treatment. The most common approach is directed toward the correction of the metabolic and respiratory acidosis. However, recent evidence that there may be severe lung damage associated with a prolonged use of high concentrations of oxygen and respirator therapy has prompted some investigators to alter their treatment of hyaline membrane disease.[1]

Cystic Fibrosis

Many things have been learned about cystic fibrosis during the past 30 years. Shwachman has summarized them as follows: "Cystic fibrosis is not a disease limited to the pancreas, but is an involvement of the exocrine glands; it is not a rare disease, occurring 10 to 20 times as frequently as does phenylketonuria; survival into adulthood and even parenthood can be achieved; the diagnosis can be made with ease, even in the neonatal period; it is a hereditary disease transmitted as a mendelian recessive; it is a serious disease affecting the respiratory system in nearly all cases; and the cause of death is most often related to the pulmonary involvement."

Improved Prognosis

Doershuk and Matthews[7] credit five advances for the improved prognosis in this disease: (1) development of dietary and pancreatic enzyme replacement therapy[12]; (2) control of the secondary bacterial pulmonary infection with antibiotics[12]; (3) early and more definitive diagnosis utilizing the sweat test[13]; (4) control of the primary obstructive pulmonary lesion[14], and (5) early institution of prophylactic therapy aimed at preventing pulmonary involvement.[15]

The nature of the basic disorder is unknown and therapy must, therefore, be nonspecific and aimed at the relief of the presenting complaints and prevention of complications. Determination of the cause of this disease is of paramount importance.

Bronchial Asthma

Twenty-two percent of all days lost from school because of chronic conditions was due to asthma. According to Dees, 1.5 million children have asthma.[2]

Antibody Selectivity

This crippling disease has been treated by hyposensitization for more than 50 years, and it is thought that such injections stimulate the production of an antibody different from the spontaneously occurring skin-sensitizing "reagin;" this antibody selectively shows greater affinity for the allergen than does the reagin present in the sensitized shock organ or cell. It has, therefore, been postulated that antigen-antibody union is consummated by the "blocking" antibody, thereby protecting cells from the damage caused by the mediators of an allergic reaction which would otherwise have taken place in some vulnerable tissue such as the bronchial tree or the lungs.[2] There are, however, many experimental and clinical observations which cannot be reconciled with this oversimplified explanation.

More recent postulates suggest that hyposensitization produces partial acquired tolerance, or immunological unresponsiveness, to some components of the antigen. This may explain decreased symptoms upon exposure to allergens and smaller degrees of specific skin reactivity. Other antigenic components appear to induce immunity as shown by rise in titer of blocking and hemagglutinating antibodies.[3]

Imbalance of Adrenergic Receptors

In certain instances, too, bacteria or their products may effect a lowered threshold to bronchospasm or altered reactivity to mediators induced by an imbalance of the adrenergic receptors of the autonomic nervous system.[4]

It has been suggested that sudden death from asthma has increased as a result of the widespread use of corticosteroid medication. In addition to the controversial effects of steroids, there has been excessive use of aerosolized sympathomimetics. The interaction of isoproteronol and the simultaneous administration of sedatives and tranquilizers leading to a "locked lung syndrome" has been reported. Early recognition of this potentially fatal condition and intervention to discontinue aerosol medication may prevent sudden death in asthma.[5]

Further study also is indicated to determine why emotional stress should be a major trigger factor in so many instances.

Pulmonary Hemosiderosis

Chronic pulmonary disease associated with serum precipitating antibodies to milk has been reported by Heiner.[6] Features of the syndrome include recurrent migratory pneumonitis, hemoptysis, iron-laden macrophages in gastric washings, sputum or lung aspirate, iron deficiency anemia, gastrointestinal symptoms and growth failure. This form of pulmonary hemosiderosis responds to withdrawal of milk from the diet.

Atelectasis

Atelectasis may arise under a variety of circumstances: (1) bronchial obstruction, either (A) extrabronchial or (B) intrabronchial, endogenous or exogeneous; (2) abnormal alveolar surface tension; (3) direct local pressure on parenchymal tissue; (4) increased intrapleural pressure; (5) neuromuscular pathology.

Etiology

Perhaps the most important cause of atelectasis is endogenous intrabronchial obstruction. This may originate within the bronchus as granulomatous tissue, most often tuberculous in origin, or mucous material, frequently secondary to cystic fibrosis or asthma.

The course and duration of such atelectasis in children depend on many factors, most important of which is the physiologic state of the obstructed bronchus. In asthmatic patients the smooth muscle spasm promotes narrowing of the lumen and facilitates obstruction. Effective medication may quickly restore the lumen to almost normal diameter. On the other hand, in bronchopneumonia, bronchiolitis, and cystic fibrosis, the inherent disease of the bronchi manifested by both edema and swelling, within the bronchi, peribronchial exudate, and the mucoid material filling the bronchus favor obstruction at various areas which, when relieved in one area, may appear in another as long as the infection thrives.[19]

The chronicity of the infection which results in damage to bronchi, and the sort of material obstructing the lumen of the bronchus also determine the outcome of the atelectasis.[19]

Bronchiectasis

It is now generally agreed that infection and obstruction of the bronchi are the two important etiologic factors in the production of acquired bronchiectasis. It is also clear that mechanical stress and obstruction alone may not result in permanent damage to the bronchi.

Tuberculosis

The mortality from tuberculosis has been markedly reduced in recent years, from 200 per 100,000 population in 1900 to less than 50 in 1940, and to only 4.9 per 100,000 in 1963.

Antituberculosis Agents

Undoubtedly, better case finding and improved living conditions have been major factors, and the advent of streptomycin in 1944 and isoniazid in 1952 has resulted in an even more precipitate drop. More recently ethionamide and now ethambutol have shown indications of being effective antituberculosis chemotherapeutic agents.

However, the new measure of the seriousness of tuberculosis is the number of new active cases; in 1962 there were 53,315 reported cases in the U.S., a figure which included an estimated 10,000 relapses. More than 11 percent of the cases reported in 1962 were in individuals less than 14 years of age.

That tuberculosis can be controlled solely by antimicrobial agents seems extremely doubtful. Certainly this cannot be accomplished with the drugs now available. There is, therefore, need for a better antituberculosis chemotherapeutic agent and either better case-finding-methods, or a more effective use of the tools now available.

Systemic Mycoses

Since 1957 amphotericin B has been used in the treatment of virtually all of the true *systemic mycoses.* However, this drug is pyrogenic, producing chills and high fever, is poorly absorbed from the gastrointestinal tract and is both hepatotoxic and nephrotoxic. The renal toxicity is dose-related and, in the vast majority of patients, irreversible. This toxicity has warranted a continuing search for newer agents. The first of these, saramycetin, a polypeptide which is administered subcutaneously, has produced marked reversal of clinical disease and cultural results in patients with histoplasmosis, blastomycosis, sporotrichosis, and aspergillosis. A study project using this drug in the treatment of chronic cavitary histoplasmosis is now in progress. A second drug, hamycin, a polyene closely resembling amphotericin B, is especially attractive since it appears to be better absorbed by the gastrointestinal route and has shown chemotherapeutic activity and virtually no toxicity in patients with blastomycosis and histoplasmosis. The most recent drug is 5-fluorocytosine, another drug for oral administration, which has been demonstrated to be chemotherapeutically active in experimental cryptococcosis and candidiasis in mice. These three agents[20] presage an era when there may be far greater choice in the treatment of the systemic mycoses in man.

Unclassified Mycobacteria

In recent years it has been established by examination of resected pulmonary lesions and suppurative lymph nodes that human disease can be caused by mycobacteria previously considered to be harmless. These pathogenic organisms are called unclassified (anonymous, atypical) mycobacteria and may be the cause of pulmonary disease resembling tuberculosis in adults and chronic suppurative lymphadenitis, particularly in children.

It is not yet completely settled whether or not these organisms may be mutations of M. tuberculosis treated with antituberculosis drugs, but the fact that many acid-fast organisms exist in nature, and existed for many years before the advent of the antituberculosis chemotherapeutic agents, indicates that this is, at best, not the complete answer.

Excision of Lymph Nodes

Prompt excision of the suppurative lymph nodes is the most important part of the therapeutic approach. In those patients with pulmonary disease who have localized lesions which have not responded to chemotherapy and who are in satisfactory general condition, resection is the treatment of choice as there is no satisfactory chemotherapeutic agent available for treatment of these infections.

Dysautonomia

Familial dysautonomia is a rare disease, and the diagnosis is still a clinical one. No satisfactory pathologic basis has been established. The recurrent pulmonary lesions are probably the result of a defective swallowing mechanism with associated aspiration. Treatment is supportive and symptomatic; no specific therapy is available.

Collagen Diseases

Among the collagen diseases the incidence of pulmonary involvement is relatively frequent and such lesions may be grouped as follows: (1) Inflammation of the pleura or pericardium. This may be either fibrinous or effusive and in Still's disease is a more common finding than is parenchymal involvement. The demonstration of a lupus erythematosus cell, in pleural fluid, is pathognomonic of that disease. In adult rheumatoid arthritis the rheumatoid factor may be present in the pleural or pericardial fluid, but in a child so affected it is not likely to be found. (2) In the lung parenchyma, fibrosis is the most common finding and closely resembles the Hamman-Rich syndrome* in histology and pathophysiologic function. The most serious and extensive fibrosis may be found in scleroderma. A distinctive disc type of atelectasis in the lung base is sometimes present in lupus erythematosus. A granulomatous lesion, seen more often in adult rheumatoid arthritis, is not as likely to occur in children. (3) Involvement of the vascular bed of the lung has begun to attract more attention. The extent of damage may range from mild fibrosis to complete necrosis and occlusion. Pulmonary hypertension and right side heart failure may result. Also, disturbed pulmonary function has been described in systemic lupus erythematosus with little or no evidence of parenchymal disease. This is presumably due to vascular disease.

Bronchogenic Carcinoma

The most highly publicized respiratory disease today, bronchogenic carcinoma, is not, strictly speaking, a major problem in children. It has, however, become increasingly common in adult life and cigarette smoking has apparently been implicated as either a major causative factor, or, at the very least, a contributing one in this usually fatal malady.

---

*See Page 1372.

The cigarette-smoking teenager is embarking on a habit which may culminate in bronchogenic carcinoma, emphysema, or other lung or cardiac disturbance which will, on an average, reduce his or her life expectancy four to eight years. According to a recent Public Health survey, smoking among teenagers has declined appreciably over the past 10 years: however, it is not decreasing fast enough and each day more than 3,000 youngsters take up smoking.

More research in this important area is undoubtedly necessary but, with the knowledge at hand, it is incumbent on all practitioners of pediatrics to make every effort to influence the adolescent to refrain from smoking.

It has been suggested that this can be accomplished in three ways: the pediatrician can approach the problem through the child's parents, through the child himself, and by his own example, i.e., not smoking himself and asking staff and visitors not to smoke in his office or waiting room.

Concluding Comments

Air pollution as the cause of emphysema and other pulmonary disease also needs further study; beneficial influence toward the correction of this problem may also be furnished by the pediatric practitioner.

The field of chronic pulmonary disease in children has changed considerably from 1938 to 1968; and it is apparent from this partial listing that progress has been great. One of the more recent advances has been in the field of pulmonary function.[21] However, the number of medical centers in which there is satisfactory equipment and skill for the study of pulmonary function in infants and young children is small, and, indeed, the presently-used studies for infants and young children must be simplified and thus rendered more available.

Chronic respiratory disease in children has changed. Many problems, not even recognized a few years ago, have already been solved; however, as is often the case, progress has merely resulted in the demonstration of other problems, to date unsolved. There is yet a long way to go.

Man

If we eliminated all the unfilled space in a man's body and collected his protons and electrons into one mass, the man would be reduced to a speck just visible with a magnifying glass.—Professor Arthur Eddington

FEATURE SPECIAL

Old Hospitals

Epidauros

Epidauros is located on the Peloponnesus about a hundred miles drive west of Athens. Historically it is an important landmark among institutions of healing because it witnessed a transition from pre-Hellenic faith healing to the rational and vaguely scientific system that was ancient Greek medicine. At Epidauros was the most celebrated temple of the God of Medicine, Asclepios, and its practitioners were priests. The priests recognized, however, that some diseases were purely organic, and apparently made frequent referrals to the physicians whose schools were located nearby.

Ruins of the Abaton at Epidauros

The temple was the center of a complex which included a sports stadium, places for musical performances, and a theatre (still in use) seating 14,000. These diversions and the pleasant surroundings of the Greek countryside prepared the patients for the drug-induced narcosynthesis and suggestion therapy practiced by the priests. The drugs were administered in a large building adjacent to the temple and called the abaton. The ruins of the abaton at Epidauros are pictured above. The building was lined with couches where the patients reclined during their diagnostic and therapeutic sessions.

While the practices of the priests anticipated modern psychiatry and psychosomatic medicine, the over-all function of the health complex is more reminiscent of a sanitarium or spa than of a hospital.

Health Effects from Exposure to Air Pollutants*

HAROLD J. PAULUS, Ph.D.†
Minneapolis, Minnesota

ONE OF THE MOST important items in our environment is the envelope of air in which we live. Until a few decades ago this necessary commodity was taken for granted. Man, in his quest for wealth and his desire to do things the easy way, has sorely abused the layer of air nearest the earth. Today we see a steadily increasing problem throughout the country, even throughout the world: air pollution.

It is small wonder that the most serious result of air pollution would be its effect on the respiratory system: mainly the lungs.

Air Pollutants

The Concentration

The concentration in the outdoor air of specific gaseous air pollutants is presently in the low parts per million range. As an example, sulfur dioxide is recorded as below 0.1 part per million by volume for greater than 95% of the time in the Twin Cities; but carbon monoxide with an average of about 35 parts per million for an hour or longer on the streets of Minneapolis and St. Paul under certain weather conditions may constitute cause for concern.

The Composition
